1.543 Lectures

2,437 Pictures—49 Color Plates

Here is such a wide choice of educational opportunities that you will find all courses of instruction which you want and need. And even if you do not feel the need of studying systematically a single one of the 57 courses, you will still find in the POPULAR EDUCATOR a vast wealth of articles as fascinating as could be found in any popular non-fiction magazine Each weekly number will give you the biggest quarter's worth you ever had!

Over a Quarter of a Million People Have Enrolled CLASS NOW FORMING

You Must Register At Once . . . Mail Coupon On Opposite Pag

57 New Easy Reading Courses Covering 4 Years High School and 2 Years College

> ENGLISH (Speaking, Reading, Writing). MATHEMATICS—PSYCHOLOGY—etc. for Only 25 Cents Each!

The POPULAR EDUCATOR is truly "the poor man's higher education" tion." Take, for example, a subject like PSYCHOLOGY If you had to attend lectures on this subject in person at a High School or Conlege, it would cost you hundreds of dollars—even an elementary te book would cost you three or four Yet the Alliance teaches you useful science for a whole year—AT A TOTAL COST OF EXA LY 25 CENTS! This is an unprecedented bargain!

IT'S NEVER TOO

LATE TO LEARN

Like Reading Any Fascinating Magazine

Nothing is more effortless and interesting than the new method of education employed in the POPULAR EDUCATOR! Your lectures come once each week on each subject in the pages of an attractively illustrated periodical. The first weekly issue includes 32 "No. 1 Lectures," in 32 different courses of instruction—from Anthropology to Zoology. The sec-

ond weekly issue brings you a similar number of "No. 2 Lectures," etc., ctc. You follow only the courses you want to learn, just as you read in a magazine only the serials that interest you most. Each course is as entertaining and informative as an expert in the subject, plus a popular writer,

can make it.

Each lecture is short enough to read at one sitting and so interesting that you retain it easily. And each is illustrated with unique photos and diagrams, sometimes copies from priceless originals in museums.

50 Years Ago in

(Condensed From Issues of January, 1889)

PHONOGRAMS-"Subscribers to whom are rented machines can have left at their door every morning the waxy tablets known as phonograms, which can be wrapped about a cylinder and used in the phonograph. On these tablets will be impressed from the clear voice of a good talker a condensation of the best news of the day, which the subscribers can have talked back at them as they sit at their breakfast tables "

MANNLICHER-"Austria, like France, has adopted for the arming of her infantry a gun of small caliber, and has chosen the model presented by the armorer, Ferdinand Mannlicher This weapon, like the French This gun (the Lebel), is of 8 mm. caliber, and fires a steel-incased ball The closing of the Mannlicher gun differs completely from that of guns provided with a bolt. The object of the inventor has been to suppress the lateral motion of the movable breech, and to

effect the opening and closing of the gun by a single horizontal motion, such an arrangement permitting of exhausting the magazine of cartridges without removing the weapon from the shoulder. . To consider but the repeating mechanism, the Mannlicher gun may, as regards its sumplicity, the strength of its parts, and its operation, be considered as the most perfect one that has been made up to the present

GAS-CARRIAGE-"At the exhibition of machinery which was held in Munich during the past year, the attention of the visitor was attracted to a vehicle with a motor constructed by the Rhine Gas Motor Works, Benz & Co., of Mannheim. This motor is driven by gas which it generates from benzine or analogous material . . . The motor . . . is placed in the rear of the three-wheeled carriage over the main axle . . . and the benzine used in its propulsion is carried in a closed copper receptacle secured under the seat, from which it passes drop by drop to the generator, and which holds enough benzine for a journey of about 75 miles. The gas mixture is ignited in a closed cylinder by means of an electric spark '

OIL-"Almost every vessel that encounters heavy seas reports, on reaching harbor, that oil was used in calming the waves with great success, and had it not been for the oleaginous liquid, the ship and all on board would certainly have gone to the bottom. Notwithstanding these multifarious statements, the percentage of vessels lost appears to remain about the same. Even if the oil has no great effect on the angry waters, it certainly produces a powerful influence upon the imaginations of the mariners. They believe it adds to their safety, fears are allayed, good judgment is preserved, and all hands work intelligently."

GAS-ELECTRIC LAMPS-"M. G. A. Tabourin proposes to the Paris Municipal Council to fit each lamp post with arc light, dynamo, and gas engine. He has contrived a dynamo of minute parts and a gas engine ten inches in diameter for coupling up with it, and would put a dynamo and gas engine in the post under each of the gas lamps, as used at present in that city, utilizing the gas supply for feeding the gas engine. . . Should his scheme prove practicable, we might be enabled to give up the discussion of burying wires, so far as high tension currents are concerned, for it would not require any.'

TORNADO-"A tornado which produced disastrous effects in many places on the night of January 9 visited a large region, including portions of New York, Pennsylvania, and New Jersey, and extending up to Canada. Among the more remarkable effects were the destruction of the Reading Silk Mills, in Reading, Pa., the

carrying away of the trusses and platform of the Niagara foot bridge, and the explosion of two gas holders in Brooklyn, N Y.'

BIG GUNS-"On December 12 last, one of the 48-ton breech-loader guns of the French battle ship Admiral Duperre burst, while firing at a target off Toulon. An officer and five men were killed. This gun was one of the finest examples of the built-up system, of which many disastrous failures are on record. Those who brag so much about these guns, and are so ready to denounce cast guns, have considerable still to learn."

(RIME—"The report of the Elmira Reformatory, now eight years in operation, will be

found worthy the attention of the scholar, as well as that of the humanitarian. It shows, so far as so limited an experience can be relied on, that the contamination of a penitentiary tends to encourage those to adopt carrers of crime who are not naturally vicious, and, per contra, that education and the absence of vicious surroundings serve, at least in the case of first offenders, to wean them from the course they have only just set out upon."

SPEED-"At a recent meeting of the Berlin Physical Society, Dr. Konig gave an account of experiments which he had made with Ottomar Anschutz on the instantaneous photography of projectiles. . . . A cannon ball was projected in front of a white screen illuminated by direct sunlight, occupying in its passage one-fortieth second During this time four negatives were taken. The firing of the cannon, the momentary exposure of the plate, and the recording of time on the chronograph were provided for by electric cur-

ELECTROCUTION-"The new law of the State of New York. ordering death by electricity as the punishment for capital offenses, went into effect January 1st."

AND NOW FOR THE FUTURE

(The hysteroid personality-always sidestepping trouble. By Paul Popenoe, Sc.D.

TWO BULLETS FROM THE SAME GUN?

I MAGES of two individual bullets, held in position under this comparison microscope's two objectives, are thrown together in the eyepiece. An "evidence" bullet is clamped under one objective and a test bullet, which has been fired from the suspected gun, under the other. Watching the two bullets in the eyepiece, the expert turns the thumb screws to rotate the bullets. If both were fired from the same gun, a point will be found where the rifling marks, or scratches, of one bullet will match those of the other. This instrument, shown reversed for mechanical reasons, is also used for checking the marks in the primers of two cartridges. It is a valuable adjunct to the work of the Technical Laboratory of the FBI, discussed in the article on page 22.

Courtesy California Agricultural Experiment Station

General arrangement of tank equipment and method of planting in nutrient solutions (above), showing the wire screen and the bedding "mattress." At right: Tomato plants grown in fertile soil, nutrient solution, and pure sand irrigated daily with nutrient solution. Photograph shows plants, after seven weeks of constant harvesting, with excellent growth and large amounts of fruit in all three media. General cultural conditions—spacing, staking, and the like—were the same in soil, nutrient solution, and silica

Plants By Liquid Culture

YDROPONICS, or the new science of tank gardening, has attained the point where it fascinates and tantalizes the enthusiastic horticulturist, be he the merest amateur or the most advanced scientific research worker. Growing plants in liquid culture media is the adaptation by Dr. W. F. Gericke, of the University of California, of a century-old method for growing individual plants for physiological research. They may now be grown under this system commercially or for the entertainment and edification of the average home-owner.

Many terms have been suggested for the "new" method, such as tank or tray gardening, aquiculture, water culture, hydroponics, and so on. Hydroponics is the designation preferred by Dr. Gericke as it is more specific than others-"hydro" meaning water and "ponos" labor. It is not, however, a method which is going to revolutionize established agricultural or horticultural procedure. Neither is it going to upset the scheme of things so that every apartment dweller and home owner will be growing his own tomatoes and potatoes, or so that those more esthetically inclined will grow their favorite chrysanthemums, begonias, and the like, in the confines of their penthouses or rooms.

For those who are sincerely interested in the scientifically controlled production of plants, hydroponics offers a fas-

Fascinating Science for Amateur or Commercial Grower... Practical Details... Formulas, Specific Instructions, Suggestions... Window-sill Culture

By C. F. GREEVES-CARPENTER

cinating means of achieving their objective in a small space such as on a window-sill or where there is a lack of soil as would be the case in the limited confines of a roof. Experimenters, however, should know that there is little evidence that better plants or larger yields can be grown in water culture than under favorable soil conditions

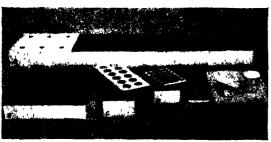

THEN plants are grown in soil, they W HEN plants are given many absorb their nourishment from many chemical compounds which are naturally present in the soil or have been added to it in the form of fertilizer. Water, acting on the introduced chemicals, releases the soluble food and makes it available for the plant 100ts. In hydroponics, no soil is present, the plant roots being immersed in water to which are added the requisite nutrient salts. There is, of course, an absorption of nutrients by the plants so that, under ordinary conditions, unless one is an analytical chemist and can determine which of the chemicals have been exhausted in the process of the growth of the plant, it is advisable to renew the entire solution frequently (for example, every two weeks) depending on the size and rate of growth of the plants. Changing the solution may be accomplished either by siphoning or by having a tight fitting spigot installed at the time the tank is constructed.

Tanks of wood, concrete, or black iron which have been coated with asphalt paint, make satisfactory containers. These may be of any length and width, but should be about six inches deep. For the sake of facility in figuring formulas, a tank two feet by six feet by six inches deep may be used satisfactorily for the initial experiments. This should first be filled with 25 gallons of water to find the water-level point. A mark should be cut into the side of the tank at this level, as it is most important that the solution not fall much below it.

A "mattress" of wire mesh—one inch for the smaller plants but two inches if larger ones are to be set out—should be coated with asphalt paint. It should then be stretched on uprights so that it is three inches above the surface of the solution as that distance will permit a certain amount of natural aeration. It is necessary, however, to supply some means of introducing additional aeration to the solution for this is an important factor in hydroponics. In the case of the small tanks mentioned, a bicycle pump inserted in the solution and worked vigorously for a few minutes twice daily will meet this requirement, according to Nathaniel Gould Harrold who has done much research work in hydroponics on a large scale.

ON top of the wire mattress should be spread a litter of straw or excelsior on which are placed pine shavings or other fine, inert material. The thickness of the actual bed of litter depends on what is to be grown in it. If seeds are to be broadcast on the surface, a depth of two inches is desirable, but where cuttings, seedlings, or bulbs are to be set out, a three- to four-inch depth offers a more solid bed for the plants.

When plants are first set out or seeds sown, the solution should have water added until it is brought up to within an inch of the bed. That this first solution has been diluted more than called for in the formula is not important. Once the white "water" roots have been formed, the solution should then be kept up to strength and three inches below the bed at the level indicated on the inside of the tank. If the plants set out in the litter are in an advanced stage of growth instead of being seedlings, the brown "earth" roots will die off when the new "water" roots are formed. All plants, seedlings, or more mature specimens, should have their roots pass-

the water culture method. They include several
sizes of iron tanks (not galvanized but asphalt
painted), a granite-ware pan, and Pyrex dish
and beaker for special small-scale experiments

ed down through the litter and wire mesh so that they are immersed in the nutrient solution.

When seeds are to be sown, the bed is first moistened with water, after which the seeds are broadcast on the surface of the litter and lightly covered. Cuttings or seedlings, on the other hand, are set out as they would be in soil. In transplanting seedlings, the soil in which they were started should be thoroughly soak-

THE new science of growing plants without soil (in nutrient solutions) has already been discussed widely, but very little more than generalities have been as yet presented to the public. After long effort, we secured the accompanying specifically detailed article; it gives full instructions and chemical formulas which will enable you to experiment in this fascinating science.

As a convenience to readers, we list below some of the companies from whom may be purchased the chemicals or ready-made nutrient mixtures for use in hydroponics.

—The Editor.

ed to permit of their easy removal without injury to the roots. They should then be gently washed free of soil particles before being set out in the litter, at which time, as has been mentioned, their roots should reach through the bed into the nutrient solution. Bulbs are planted in the litter as though it were soil, and they will soon put on a healthy root growth if they are in good condition. At all times the litter should be kept moist but never saturated (waterlogged), for that would exclude air from the plants as well as create a tendency for unfavorable bacterial decomposition.

Of course, it is not possible to guarantee 100 percent success, and a lot of trial and error may be necessary before one finds the answer to the successful appli-

cation of hydroponics to his particular plants, locality, air. temperature, and humidity conditions. Such technicalities as the character (analysis) of the water, the adjustment of the chemicals in the nutrient formula to counteract undue alkalinity, and the like, will enter into the growing of plants by this technique. The pH value (the degree of acidity or alkalinity) of the water is a factor of the utmost importance in growing plants by hydroponics and this may be

easily determined by the newly developed litmus papers that have recently been introduced on the market. If the water is alkaline, either dilute sulfuric or nitric acid should be added to bring the reaction of the solution to pH 5 or 6, as shown by simple acidity determining kits. These reactions, pH 5 or 6, are only slightly acid, and the solution should be carefully held to about these points.

The next consideration is the choice

of nutrient salts. Many formulas have been packaged and sold through seed supply and mail order houses. Trials may be made with these to determine whether they are suitable for the particular plants it is desired to grow, as well as for the locality and other environmental conditions. If one wishes to try some of the standard formulas which have been developed by various scientists, there are several which have been successfully used by Dr. John M. Arthur of the Boyce Thompson Institute for Plant Research, Inc., at Yonkers, New York.

SOLUTION developed by Dr. J. W. A Shive which is easy to prepare and has been very successfully used is given in Formula I. Another, which was developed by Dr. Arthur and his associates at the Institute, is given in Formula II. This latter formula is used for growing many plants rather than for single specimens. Formula II is in ounces avour dupois and is calculated for 25 gallons of solution, as is the Shives' Formula (1). Dr. Arthur has found it desirable to add traces of iron, boron, and manganese. Iron chloride, boric acid, and manganese chloride should be made up in saturated solutions and these solutions added to the formulas at the rate of ten drops of boron, five drops of manganese, and ten drops of iron to each 25 gallons of solution. Chemically pure salts need not be used in preparing the formulas as ordinary fertilizer salts will be found equally effective.

Prof. D. R. Hoagland and Dr. D. I. Arnon, of the Agricultural Experiment Station, College of Agriculture, University of California, suggest two formulas as being suitable for growing many kinds of plants. The "T.C." formula is given in Formula III, and the Station states that it "may often be preferred

because the ammonia salt delays the development of undesirable alkalinity.' The ammonium and magnesium salts should be of technical grade, while the other two are fertilizer salts. The addition of the salts to the water should be made in the order given. To this formula should be added iron, boron, manganese, zinc, and copper. While copper and zinc are essential for plant growth, enough of these elements will usually be present as impurities in the nutrient salts or water so that the addition of copper or zinc can be safely omitted.

The boron and manganese solutions (also the copper and zinc solutions, if used) should be added in the recommended proportions each time the nutrient solution is changed.

FOR the first of these five added chemicals, a level teaspoon of iron tartrate should be dissolved in a quart of water, and this should be added at the rate of a cupful to every 25 gallons of solution each week, or more frequently should the plants appear to be of poor color,

For the boron solution, a level teaspoon of boric acid should be dissolved in a gallon of water, and 11/2 pints of this should be added to every 25 gallons of nutrient solution.

For the manganese solution, a similar quantity of crystalline chemically pure manganese chloride should be dissolved in a gallon of water. Prof. Hoagland and Dr. Arnon recommend the dilution of one part of this solution with two parts of water by volume and the addition of a pint of the diluted solution to each 25 gallons of nutrient solution

For the zinc solution, a like quantity of crystalline chemically pure zinc sulfate should be dissolved in a gallon of water, and four teaspoonfuls of this solution should be added to each 25 gallons of water.

For the copper solution, a teaspoonful of chemically pure copper sulfate should be dissolved in a gallon of water. This

should then be diluted at the rate of one part to four parts water, and one teaspoon of the diluted solution should be added to each 25 gallons of the nutrient

Aside from the chemical elements derived from air and water, plants require at least eleven other elements. This is true, of course, whether the plants are grown under hydroponics or in soil. These chemicals, in the case of hydroponics, must be added to the water in proper form and concentration, so care must be exercised in this respect. In the natural process of growth, it will be found that certain plants require larger quantities of some chemicals than of others and it is also true that at certain stages in their growth they will absorb more of one chemical than of another. In order to avoid the tediousness of continual analyses of the solution, one practice is to empty the tank once every two weeks as has been mentioned, but, even so, water will have to be added in the interim to keep the solution at the desired level

When the tank has been drained for one of these semi-monthly changes, it should be half filled with 121/2 gallons of water, then the nutrient chemicals should be added and the balance of the water should, when possible, be run in under pressure to insure an even distribution of the chemicals throughout the solution. The entire operation of draining and replenishing the tank should be done as quickly as possible to avoid any chance of the roots drying out

Soil-borne diseases are, naturally, nonexistent in hydroponics, but insects, fungi, and bacteria are apt to be just as provalent as in plants grown in soil Mildew is likely to prove troublesome due to the humidity which is possibly increased by the moisture in the tank, but using dusting sulfur on the plants will keep this in check

Temperature as well as strength and

When tall-growing plants are raised in nutrient solutions, firm supports must be fastened to the tanks

duration of daily sunlight are factors equally important whether plants are grown by hydroponics or in soil. Recent experiments in supplemental artificial lighting have been worked out by Lawrence C. Porter and his associates at the General Electric laboratories. These indicate that on cloudy days and during the winter days of shortened hours of sunlight, supplemental electric lighting is decidedly beneficial if applied for three hours every winter or cloudy day. A metal reflector should be bent so that the light beams are equally distributed over the tank area, and a 150-watt Mazda lamp will suffice as the light source. This should be suspended on a pulley above the tank so that it may be raised with the growth of the plants.

OMATOES, potatoes, melons, beets, TOMATOES, polacoco, spond very favorably to the controlled conditions which prevail under hydroponics. Roses, chrysanthemums, begonias, gladioli, and many other flowers may also be grown with marked satisfaction.

Hydroponics offers an intriguing field of investigation for the enthusiast. Once flowers or vegetables are successfully grown by this unique cultural technique. experiments may be made in attempts at controlling the flavor of vegetables or the color and odor of flowers, but with what success only individual research will show. Conditions are certainly more closely controlled than in soil, and with that as a starting point the investigator has much in his favor.

Radium Hounds

Devices that Bay on the Trail of Lost Particles of a Dangerous Element... When a Pig Ate Radium... An Elephant Easier to Hide Than Stolen Radium

By ROBERT B. TAFT, M.D.

Author of "Radium-Lost and Found"

ADIUM is a gleaming sword in the treatment of disease, but it is a two-edged sword that has an unfortunate habit of getting lost. If the timest particle disappears, it is not only costly to replace (radium is worth 24,000 times its weight in pure gold) but also becomes an immediate menace to the lives of those who may unwittingly come in contact with its destructive rays. Actually, 107 cases of radium losses have been reported to me by members of the medical profession during the past few years. The potential danger lurking in a few milligrams of lost radium is so great that scientists have invented ingenious devices to recover it.

Radium is always handled in such minute quantities that occasional loss is inevitable. Thus, in treating cancer patients, doctors rarely use more than 100 milligrams—just about enough to cover the head of a pin. The amounts are so small that they must be mixed with other powdered salts and applied in tubes and needles made of extremely thin platinum or silver. On the cap of these tiny containers is an eyelet to which a piece of fine wire is fastened. The wire facilitates handling, but is only a partial insurance against loss.

Startling results in tracing lost radium are obtained by the use of some exceedingly clever devices known as "radium hounds." A rudimentary but effective "hound" is an electroscope consisting of a piece of gold-leaf with one end fastened to a metal support and the other hanging free. When electrically charged, the gold-leaf is repelled from the metal rod, and stands at right angles to it. Should the instrument be brought near a particle of radium, however, the electricity is partially discharged and the gold-leaf begins to drop. When the instrument is brought very close to the radium, the gold-leaf drops back to its normal position.

A tiny silver needle containing \$1000 worth of radium was salvaged at the Presbyterian Hospital in Newark, last year, by the use of this modern divining rod. The needle had accidentally fallen

into a pile of soiled dressings during the treatment of a cancer patient. Doctors discovered the loss only after the refuse had been thrown into the hospital inemerator. The silver container, of course, had by that time melted away; but since radium is virtually indestructible, even at terrific temperatures, hospital authorities knew that the missing supply was still intact somewhere in the roating blaze. When the furnace had cooled, the ashes were carefully removed in buckets and placed underneath the "radium hound "No response came until the 23rd bucketful was reached; at that point the gold-leaf fluttered-and dropped. In a few minutes the search was successfully completed.

THE moment a quantity of radium is reported missing, everyone concerned leaps into action. A hasty preliminary search of the laboratory may be made with a piece of willemite or an ordinary fluoroscope. Willemite is a fluorescent mineral which glows in the presence of radium rays. The fluoroscope reacts similarly, but neither method is effective except at very close range. If these fail, the more sensitive "hounds" must be commandeered.

Sometimes, when the gold-leaf electroscope is not sensitive enough, a device known as the Geiger-Muller counter is brought into play. This instrument consists of a tube connected at one end to batteries supplying an electric current; the other end leads to a system of vacuum-tube amplifiers. Radium rays, if present, reduce the resistance between the two ends; the electrical impulses thus set up are magnified to operate a loudspeaker. So sensitive is this instrument that 20 milligrams of radium can be detected at a distance of 135 feet.

While treating a patient in a Canadian hospital, a doctor lost a brass capsule containing 50 milligrams of the precious element. A preliminary check-up showed that the capsule was lodged somewhere in the city's sewage system. Engineers supplied the physician with a map of all drain pipes, most of which were more

than 15 feet below the street surface. Armed with a Geiger-Müller counter, the doctor then started from the hospital and slowly followed the path of the pipes as marked on his map. In the middle of the third block the clicks of the counter suddenly began to grow in volume and speed; and the trail grew warmer until the rapidity of the count told the physician that he was directly above the lost radium. A worker descended a nearby manhole and fished out the lost capsule.

In a Sioux Falls hospital a few years ago, a fantastic radium hunt began after a nurse momentarily placed a radium needle on the surgical table. The needle accidentally stuck to a piece of adhesive tape and was thrown away with a pile of refuse. By the time the loss was discovered, the rubbish had been carted off and dumped on a pig farm 40 miles away. Two University of Minnesota physicists were hurriedly dispatched to the farm. where they began testing endless piles of rubbish with their electroscopes. In the middle of their search, the gold-leaf began to quiver, but a moment later it resumed its normal position, despite the fact that the electro-cope itself had not been moved. This recurred several times before one of the searchers noticed that the leaf quivered only when the herd of feeding swine nosed by. Acting on the unexpected clue, they divided the 500 pigs into groups and repeated the test until the leaf fluttered agam. By the process of elimination, they finally reached one solitary pig. A butcher was called and the radium was recovered.

Uncanny as these detectors already are, technicians strive constantly to per fect their accuracy and sensitivity. A few years ago, the National Physical Labora tory in England devised an instrument called the "radium hen"—so named because the presence of radium makes the apparatus cluck just like a hen after it has laid an egg.

SCIENCE, which discovered radium, has developed virtually fool-proof means of safeguarding its use, and recovering it if lost. Sometimes radium is carried off by sewage pipes and lost in the ocean or rivers, where detection is nearly impossible. But in such cases, the radium has been deposited where it at least can do no harm. Apart from the financial loss, no one need worry.

Despite the fact that radium is worth \$25,000 a gram, with the present United States supply only 300 grams (roughly, 11 ounces) doctors seldom worry about loss because of theft. Disposal of the stolen product, for one thing, would be practically impossible. The market is confined almost exclusively to the medical world, and any irregular source could be immediately traced. A stolen elephant, moreover, would be easier to hide than a pin point of radium. The

OUR POINT OF VIEW

It's On the Way

TELEVISION, problem-child of the laboratory, appears to be ready to turn the long-promised corner Announcement has been made that television (now called "video") programs will be presented on regular schedule by two or more eastern stations, beginning next spring. Congratulations to the earnest workers who have made great strides in this science—and particularly for their commendable reluctance prematurely to foist an imperfect service on the public. May the regular programs be as fine in quality as the admirable private demonstrations which we have recently seen!

Radio's Influence

FOLLOWING the recent "radio terror" broadcast, commentators and editorial writers did a pretty thorough job of plumbing the reasons for the public's unreasoning, instant credulity Largely, it was assigned to a juttery state of nerves brought on by the war crisis through which the world had just passed. Such criticism was levelled at the producers of the air-drama and such vociferous demands were made for broadcasters to censor themselves that it is hardly likely that such a dramatization with such possible consequences will be repeated.

Yet in all our wide reading about the unfortunate incident, we recall not one hint of certain broader implications Too much was said of war psychosis and nothing of the normal human equation We had thought that the Brooklyn Bridge would find no "buyers" now, yet the confidence men who periodically "sold" that structure in the old days had a harder job than the broadcasters of H. G. Wells' drama, for the latter explained over and over what they were doing. It begins to look as though there must be something inherent in the radio, in the mystery of a voice coming from an unseen speaker through a gadget of wires and tubes, that inspires unquestioning confidence. Otherwise, despite the war psychosis explanation, why did not more people question this particular broadcast as did one man we know who did not hear the original announcement? When his family got excited, he told them: "Turn to other stations. If it's true that a great meteorite has fallen, all stations will be hysterical about it."

The lesson that seems to be taught here more dramatically under what might be called purely test conditions than ever before-is that a few words over the radio, dramatized just so, exert a powerful influence over millions of our people With a given set of conditions, a psychosis carefully built up by radicals. reformers, politicians, or "revolutionaries" of whatever stripe, it would appear that only a few suave promises, hysterical diatribes, or epithets hurled at this or that would set the people off. Perhaps the most important thing is for all who use the radio in any way to look in ward, clean their own houses, and try to do some honest thinking and honest talking If they do not, there may be a revolution among listeners-a revolution of the radio switch in a counter-clockwise direction until a click is heard -F.D.M.

Premature

PREQUENTLY during recent years this journal has been urged by some of its readers to conduct certain scientific investigations, chiefly of "dowsing," or water witching for underground water with the traditional forked hazel bough

What, from an editor's point of view, would provide more fun—not to name worther considerations of science and usefulness—than temporarily to aban don hard sedentary work at a desk in the heart of a greatesty and take to the open fields to test the abilities of dowsers!

No adequate investigation of water witching ever has been made. True, Sir William Barrett and William Besterman, in their book "The Divining Rod," report on numerous tests. Water is located, they finally conclude, by those who are endowed with a subconscious supernormal faculty, cryptesthesia. Unfortunately, the book reads like the special pleading of advocates. It largely lacks objectivity. It leans, Science did not receive it favorably

To investigate dowsing, we have been urged, simply test dowsers in the field results count. But this scarcely seems necessary since there is no question that dowsers do locate water. So, however, do others, and there is the rub. To prove dowsing would require something different—something that would provide an entirely undebatable answer. For this the human factor—the hands holding the forked bough and the brain behind the hands—would have to be eliminated. Science asks for pointer readings on unsentient apparatus. Apparatus has no motives. It does not even fool itself.

Just how would such apparatus be designed? On exactly what working principle? We doubt whether anyone knows (some appear to think they do, and bring

up such terms as "magnetism," "attraction"—unexplained in themselves). Until a working principle behind dowsing 14 found (if there is one) science is unable to proceed. An investigation would be fun but that is all it would be.—

A G I

How Much?

HOW much will it cost?" is a question that has wrecked many a promising piece of projected research Here should be a common meeting ground where science and industry see eye to eye in their efforts toward technological progress, yet all too often it is the stumbling point where progress is halted. It is the exceptional case where a research worker can say definitely just how long a certain project will take to complete or what his expenditures will be before he reaches his goal Even the goal is often indefinite and frequently changes as work progresses Research can in no way be compared with industrial production.

If industry is to realize the greatest benefits from the work of the pure scientist—who, indeed, is the dominant though retiring figure of present-day industry—he must be freed from the fetters of financial limitations, must be permitted to pursue his studies and experiments with a minimum of interference. By permitting such a course, the farsighted industrialist will find that his research laboratory will pay big dividends, often in a way that was unthought of when the work was started.

Charles F. Kettering, probably the best known research worker in the nation, recently uttered a plea for a better understanding between those who pay the bills and those who delve into the secrets of nature. Realizing that costs must be met, records must be kept, he suggested that industry in general apply the actuarial type of accounting to research, rather than cost accounting. Thus the costs of research would be allocated by a statistical average taken over a number of years and over a number of research problems

As industry gains a greater appreciation of pure science research and its effect on the applied science that results in new products, expanded markets, and better business conditions, costs of research will assume a less important place in the scheme of things and the laboratory worker will be encouraged to pry into many corners of which little is known, unhampered by the specter of dollars and cents.—A. P. P.

THE CONQUEST OF THE

Palestine's Biblical Lake, Containing Sufficient Potash and Other Chemicals to Supply the World for 2000 Years, is Now Being Actively Exploited

THE successful completion of extensive works upon the southern shores of the Dead Sea, in Palestine, for the recovery of potash and other valuable salts, similar to, but on a much larger scale than, the works established at its northern end a few years ago, calls attention to what has been done in winning these prized salts from the brineladen waters of this remarkable inland lake. Hitherto, potash has been obtained chiefly from Germany and France; more recently from the United States and Spain.

Until quite recently most people looked upon this hot, barren, and isolated region of the Dead Sea as of little value commercially. True, the waters were known to be impregnated with valuable salts, such as potash, bromine, and magnesium chloride, but the problem was to recover them on a commercial scale To extract these coveted salts called for considerable pioneer and experimental work extending over many years. It was necessary to ascertain the exact salt content of the waters and whether these salts could be recovered by solar evaporation. This called for years of patient study and research in a hot and desolate region many miles from any center of supplies, and these had to be brought in.

Potash is a white powder, and approximately 90 percent of the potash produced to-day is used as a fertilizer. It can be used in the natural state, or mixed with phosphates or nitrates. It also finds a place in the manufacture of explosives

Bromine is a dark, reddish brown, highly corrosive liquid, which is easily made volatile, giving off heavy vapors, It enters commerce largely in the form of its salts, of which sodium bromide, potassium bromide, and ammonium bromide are used in almost every civilized country. The principal outlet for bromine, however, is as ethylene dibromide, used with tetraethyl lead to form anti-knock compounds (that is, Ethyl fluid) which, when added to gasoline, assure smooth running in high-compression automobile engines used in most modern cars.

The Dead Sea, a great storehouse of valuable chemicals—a veritable Eldorado—forms part of a depression, a rift, in the earth's surface. The rift extends much farther than the boundaries of Palestine, running down the Jordan Valley and the Dead Sea to the Gulf of Akaba and, crossing to the African continent, reaching the great lakes in Central Africa. In the neighborhood of the Dead Sea this depression reaches its greatest depth, the surface of the Dead Sea being 1290 feet below the level of the Mediterranean. It is the lowest lying body of water on the face of the globe.

THE region of the Dead Sea is weird yet awe-inspiring, with its mountains of rock salt, its picturesque gorges, its caves, quaint little oases, and hot springs. There are the hot baths of Kalirrhoe where Herod came, when stricken with his last sickness, in the hope of finding that recovery which he sought in vain. On both the western and eastern side the Dead Sea is hemmed in by towering barren mountains, with scarcely any shore line. Everywhere there is evidence of great volcanic disturbances in past ages. No doubt the presence of sulfur, bitumen, and possibly oil, played their part in

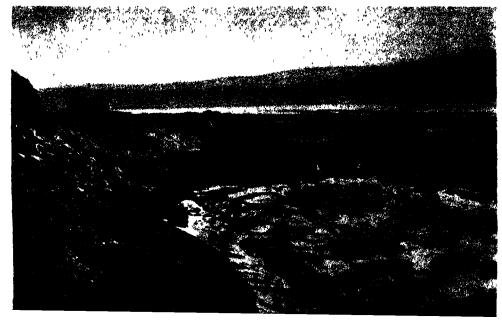

causing the overthrow of Sodom and Gomorrah and the other cities of the plain. Where Sodom and Gomorrah stood no one really knows. Ruins of a lost city have been found at the north-western corner of the Sea, and some scholars believe they mark the site of either Sodom or Gomorrah. Others place the site of these cities at the southern end. The name of Sodom has, at any rate, been given to the new potash camp at that end. On the north-western side of the Sea rises Mount Nebo, from which Moses viewed the Promised Land.

The Dead Sea has a length of about 50 miles, an average breadth of nine miles, and a maximum depth of 1300 feet. It is estimated that, from the River Jordan and the other smaller streams, there pours into the Dead Sea on an average over 280,000,000 cubic feet of water daily.

As the Sea has no outlet, this water is entirely dispersed by solar evaporation—evidence of the great heat of the region. The waters of this strange lake are so salt and bitter that no fish can live in them, and their specific gravity is so high that it is impossible for a human body to sink. That is not to say that a person could not drown in the Dead Sea. Whereas in the oceans the percentage of mineral salts is but 3½, in the Dead Sea it reaches no less than 25 percent. Place a fresh egg in the water and it will float away like a cork.

When the potash company started operations at the northern end of the Sea,

Dead Sea

By HAROLD G. SHEPSTONE, F.R.G.S.

they required the whole of the area there for their works. This was the spot visited by tourists from Jerusalem. So a small area at the north-eastern corner of the Sea was set apart as a tourist rendezvous known as Kallia. It developed into a thriving resort, with restaurants, cafes, bathing and boating facilities and with a fleet of motor coaches carrying visitors to and from Jerusalem some 25 miles distant by road.

A popular time to visit Kallia is at full moon, when the writer has counted as many as 200 bathers in the water at one time. During one of the writer's visits to Kallia a young woman was drowned within a few feet of the shore and within

of the lake. Laying out these works, with their model settlement where some 500 Jews and Arabs with their wives and families dwell, was no light undertaking. Roads had to be built to the site, and a power-house, pumping station, refinery, and workshop erected. The desolate Dead Sea region suddenly became a place of great activity.

For two miles along the shore, and running back on either side of the River Jordan, are the evaporating pans, each from 7½ to 30 acres in

A sluice gate between the pans, by means of which the level of the flow of the brine is regulated. Note the incrustations of mineral salts on the timber work

her own depth. Apparently she had stumbled when entering the water, and was no doubt rendered partially unconscious through the pain set up by the water reaching the eyes. Her body did not sink, but her head, the heaviest portion, was under water. At Kallia no diving is allowed and bathers are warned not to get the water into their eyes. The workers at the potash plants are not allowed to stay in the water more than a quarter hour at a time unless there are facilities for a douche in fresh water.

As a result of the experiments carried out by Mr. M. A. Novomeysky, the managing director of Palestine Potash, Ltd., a complete plant for the recovery of potash was first erected on the northern shore

extent, covering a total of more than 1200 acres. The brine is pumped into these pans by a great suction pipe laid on the bottom of the Sea and extending outward to reach a depth of 175 feet. Soundings showed that at this depth the water contains twice as much potash and bromine as on the surface. The pipe is 2500 feet long, 30 inches in diameter, and laying it proved to be no small feat. After sections of the pipe had been welded together on the bank, six days were epent in launching it, due to unfavorable weather and other causes. It was necessary to send down a diver to bolt the sections together. The Syrian diver employed found it impossible to work in the brine-saturated waters and an experi-

Jebel Usdum's cliffs of salt towering up just behind the camp established at the newer and larger plant at the southern end of the Dead Sea. Atop the salt hill is 1 lookout post in which are guards who watch for Arab attackers

enced diver had to be brought out from England. On the other hand, at the newly established works at the southern end of the Sea, the water is being pumped from the surface, as here it was not found necessary to lay a pipe to any particular depth.

At both the northern and southern plants the brine is pumped into the farthest and highest of the pans, which are so arranged as to allow a constant slow movement of the brine from one pan to another, in a zigzag, downward flow toward the Dead Sea. The pans are provided with sluices, permitting regulation of the flow or temporary shutting off of any of the pans when needed. In the course of such a tardy flow, the brine becomes more and more concentrated. Common salt is the first salt to be deposited in the pans. On further concentration carnallite, or crude potash, separates out.

The carnallite is harvested mechanically as soon as three to four inches have been deposited. It is then conveyed to the field mixers in the refinery, where it is decomposed with cold water and, on further treatment in the refinery, muriate of potash is produced to any de sired degree of purity. The brine left after carnallite separation—the "final brine"—contains the entire bromide in a concentrated form of magnesium bromide, which is conveyed by pumping to the bromine factory, where liquid bromine of a high degree of purity is ex-

Arab workmen on the carnallite fields, heaping up the carnallite near the railroad tracks in readiness for its removal. They are wearing high rubber boots to protect their skin against the harmful effects of the heavily concentrated mineral sults

tracted from the magnesium bromide.

Another portion of the final brine is left to concentrate further in pans till a specific gravity of 1.37 is reached. This occurs during the hottest part of the summer, when the thermometer touches as high as 160 degrees, Fahrenheit. At this point crystals of magnesium chloride separate out in the shape of long needles which are collected and further treated for the market. The remaining brine contains all the calcium chloride, which can also be extracted by a fairly simple

method.

THE present output of the northern plant is 30,000 tons of potash and 1200 tons of bromine a year Since the flat land at the northern end of the Sea, suitable for building pans, is limited, the company acquired about 23 square miles of ground at the southern end of the lake, where, during the past three seasons, engineers have been busy, as already stated, building a power-house, pumping stations, refinery, warehouses, laying out the necessary evaporating pans, and establishing a camp for the workers

The settlement is at the base of Jebel Usdum, a mountain of rock salt six miles long and from one and one-half to two miles wide

The establishment of a model commercial plant and settlement in this hot and isolated region presented many problems. A whole season was spent in surveying the section. Then came the erection of a pier Everything had to be conveyed to the site by water from the northern end of the Sea. The transference of the necessary lumber, machinery, and stores was a formidable task in itself, for the local resources furnished nothing. At the end of two seasons' toil, however, the evaporating pans had been

built, brine was being pumped into them, and potash was being sent in specially-built barges to the northern end of the Sea for shipment to the world markets.

While it has been found necessary, owing to the great heat, to send the staff and workers at the southern end of the Sea away for a week's respite every fourth week during the summer months, the Dead Sea region can scarcely be described as unhealthy. The air is much warmer at the southern end of the lake than it is at the northern end, the thermometer rising in the summer months to as high as 160 degrees, Fahrenheit, at midday and seldom dropping to below 100 degrees during the night. Lying 1290 feet below sea level, there is more oxygen in the air-six percent morethan at normal sea level. There is an

entire absence of fog; the atmosphere is dry and the air clear. There are no mosquitoes or troublesome sand flies. As the salts obtained from the waters form the basis of many drugs used to combat and cure disease, it is thought that breathing the air that contains them in suspension is beneficial, while the waters are also highly radio-active, comparing favorably in this respect with the waters of those spas that are esteemed for their curative properties. These are the reasons given by scientists who have investigated the matter for the healthy condition of the toilers at the Dead Sea. Malaria and other diseases attributed to tropical conditions are unknown among them.

As already stated, it is believed that, with their southern plant working at full capacity, the company will be in a position vastly to increase the present output of potash, and other salts in proportion. British government experts who have made independent investigations declare that there are more than 1,000,000,000 tons of potash, over 800,-000,000 tons of bromine, and other salts in proportion, in this single sheet of water-sufficient to supply the world's present needs for the next 2000 years. Moreover, these valuable salts are continually being added to. They are steadily brought down by the Jordan in solution from the hot springs of Tiberias and also pour into the lake from the hot springs in the immediate neighborhood The Jordan alone pours into the Dead Sea about 40,000 tons of potassium chloride yearly.

WITH the exception of a single raw material—Diesel oil for generating electric power—all the raw material-used in the production of the potash and other valuable salts—that is, the waters of the Dead Sea, the sunlight, and fresh water from the Jordan or nearby wells—are available on the spot.

Potash being loaded into a 100-ton barge at the southern pier, immediately below Jehel Usdum, in pregnantion for towing to the northern end of the lake

More Than One Man's Fun

ALAMAZOO, Tacoma, and Washington, D. C., from which the photographs on this page originate, are but three American centers where clubs of amateur astronomers and telescope makers thrive today. There are similar clubs in at least three-score others. Ideally combining the scientific and mechanical urges with the pleasure of hobnobbing with fellow hobbyistsstudying astronomy, for example, in meetings, building telescopes together and thus throwing mutual light on each other's difficulties-these clubs of amateurs provide an outlet for what some believe to be a wish, perhaps unconscious, on the part of many, that they had chosen

Right: Tacoma
Amateur Astronomers with
home-made telescopes meeting
in Rainier National Park with amateurs from nearby
towns for a weekend of
observing

Below: National Capital Amateur Astronomers' Association, with 71 members (of whom 17 men and seven women made their own telescopes) meet near the National Observatory

Above: Kalamazoo Amateur Astronomical Association contains 36 members who own 21 telescopes made by themselves. A monthly meeting in some member's home permits observation; dicussion and talks on astronomy or optics are given. A "night club" of this kind is less damaging to purses than another kind

Persons of all vocations and ages are brought together by this common interest in astronomy and optics—though the actual telescope-making phase of these astronomical club activities seldom finds

a career in science when they were youths.

astronomical club activities seldom finds practical expression in youths less than 16 or 18 because it is work that requires more maturity, more general judgment and especially more patience and tenacity than most minors have developed. In fact, these same qualities, in the measure usually given an adult, rather than special skills beyond quite common "handyman" grade, are the main desideratum. The work is not easy—rather it is quite difficult—and this is the probable reason why it has made such strong appeal to persons of better than common intelligence. A department for the amateur "telescoptician" is published in every number of Scientific American.

THE IMAGE-SLICER

VERYONE realizes that the astronomer's Enemy No. 1 is cloudy weather; but the weather is his Enemy No. 2 as well. Often, especially in a climate like that of the eastern United States, the sky will be clear from horizon to horizon, and the stars brilliant on a dark background, and "snappy"—and the experienced observer takes one look at the violent twinkling even of stars in the zenith, shakes his head, and does not even bother to open up the observatory dome.

Sad experience has taught him that on such a night of "bad seeing" the image of a star will not come to any sharp focus If he sets his eyepiece to the position which, on good nights, gives a sharp, clear image, he will see instead a large, fuzzy, and continually changing spot of light—shrinking perhaps for one good moment to something like a respectable star-image, and then exploding into a great flickering patch. Nothing has happened to the star, of course—the Earth's atmosphere is to blame.

WHEN the air is quiescent and steady, light passing through it is deviated by refraction, but by a fixed amount (depending upon the angle which the rays make with the vertical), so that the stars are clearly seen, but shifted in apparent position. Allowance for this shift demands more or less tiresome calculations, but can be fully made. But when the air is turbulentfull of streaks of different density-the rays from the star which enter different parts of the aperture of the telescope will be differently deviated. Each small bundle of them will come to a focus at a point corresponding to the direction in which it entered the instrument; but the combined effect of the whole will produce a blurred image, which will change continually as the wind carries different bodies of air across the line of sight. Windy nights are therefore unwelcome to the observer. Things are worst of all when the wind changes abruptly as the height above the ground increases. Where one layer of air slides over the other violent eddies are formed. The aviator flying through feels "bumps," and the astronome:, far below but trying to look through, gives up any precise work.

On an ordinary night the telescopic image will be fairly sharp, though blurred at times, and will dance about more or less. Observers are accustomed to describe the degree of steadiness by

A New Apparatus Used with the Spectroscope Cuts Star-Images into Sections, Rearranges these End to End, and Multiplies the Efficiency Very Greatly

By HENRY NORRIS RUSSELL, Ph.D.

Chairman of the Department of Astronomy and Director of the Observatory at Princeton University. Research Associate of the Mount Wilson Observatory of the Carnegie Institution of Washington

a scale of "seeing," ranging from zero on a bad night such as has been described to 5 on an ideally good one Such estimates are purely empirical, but by comparison of the figures assigned by different observers with the same telescope, or by the same observer with different telescopes, at the same place

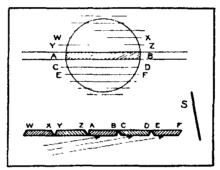

Figure 1: Showing diagrammatically the principle of the image-slicer, as redrawn from the author's sketch

and time, a fairly reliable scale can be derived.

A more open scale, running from zero to 10, has been suggested; but it has been said of someone that, being of a cautious temperament, he saved the designation 10 for conditions so ideally good that they never could actually happen, kept 9 for a situation so good that it never did happen, and called the very best nights "seeing 8."

When the seeing is bad, observations which demand the resolution of fine detail, such as measures of close double stars or study of the planets' surfaces, are impossible and most others are seriously disturbed. For example, if one seeks to photograph the faintest stars accessible with a great telescope—say the 100-inch-even moderately poor seeing expands the images on the plate so that a longer exposure is necessary to get the faintest of them above the "threshold" of visibility. This wastes time. Moreover, if the exposure is long enough to produce fogging of the plate by the general background of the light of the

night sky (about half of which originates in the Earth's atmosphere) there is no gain in prolonging it further. The very faintest stars can therefore be photographed only on steady nights.

Bad seeing is also a serious enemy to the spectroscopist. To produce a sharply defined spectrum, in which lines closely adjacent in wavelength are separated, the light must enter the spectroscope through a narrow slit, only a few thousandths of an inch wide. The image of the star is thrown on this slit by the main telescope. The front surface of the slit-plate is polished, and reflects the light which does not enter the slit back to an appropriate guiding eyepiece so that the observer can see what is happening. If the seeing is very good, the star-image will be small-almost a point of light-and by careful use of the slowmotions of the telescope it can be kept upon the slit so that not much light slops over at the edges. But this happens only on the best nights. Usually the starimage is more or less fuzzy, overlaps the slit on both sides, and dances about faster than the guiding devices can follow it, so that a large part of the light is wasted. Under working conditions, 10 percent or even less may get through into the spectroscope.

To widen the slit lets in more light, but only at the expense of spoiling the sharp definition of the spectrum—which is, above all else, needful in many types of investigation.

To put a condensing lens in front of the slit, and make the star-image smaller, is possible; but this would make the angle of the cone of light which converges upon the slit greater. To get the whole of this wide angle beam, diverging behind the slit, upon the lenses and prisms (or mirrors and grating) of the spectroscope demands changes in its optical construction; and, when the effect of these is calculated, it is found that they just undo any gain which might otherwise be hoped for.

The problem of getting more light into

the slit, under given conditions of seeing, had been given up as hopeless; but it has just been attacked successfully, by a quite different method, by Professor I. S. Bowen, of the California Institute of Technology-widely known for his identification of the principal nebular lines a few years ago. His solution is simple in principle—though rather complicated to explain in detail. The spectroscope slit, crossing the middle of the (roughly) circular image of the star, cuts out a narrow slice from it, AB, Figure 1, upper drawing, and throws away the rest. Suppose that we could in some way cut out parallel slices of equal width, such as CD, EF, WX, YZ, and divert the corresponding light into other parts of the slit, arranged in tandem along its length, as illustrated in the lower part of the figure. We could then get all the light through the slit (barring the inevitable losses due to instrumental imperfections) and gain correspondingly.

The actual slicing of the image is accomplished with ingenious simplicity by means of a system of small mirrors, each set up above a part of the slit, such as AB or EF, and with its reflecting surface inclined at an angle of 45 degrees so that a beam of light traveling parallel to the slit-plate, in the direction indicated by the arrows, would be reflected straight down into the slit.

SUPPOSE we could set up the spectroscope itself with its axis at right angles to the telescopic beam of light, so that the latter followed the direction of the arrows, and would form an image like that in the upper drawing upon a screen set up at right angles to it, as represented by S in the lower drawing (where the screen is supposed to stand at right angles to the plane of the paper). Each of the small mirrors would then automatically cut off a slice of this image, and reflect it into the slit (away from the reader), and the problem is solved.

In practice it would not be convenient to put the spectroscope in this position; but it is very easy to catch the telescopic beam (which in Figure 1, lower drawing, must be supposed to be coming downward at right angles to the page) upon a simple mirror which turns it sidewise in the direction of the arrows.

The tiny mirrors must be only about 1/30 of an inch long, and but a few thousandths of an inch wide. Such small surfaces, standing alone, could not be accurately enough figured and adjusted; but by making a series of larger blocks of glass of the proper shape and mounting them so that the end of each one projects just the proper number of thousandths of an inch beyond the one preceding, the arrangement may be practically realized. The detailed arrangement, by which each mirror-surface is fixed exactly in the right position, so

that it takes its own slice of the image without either overlap upon the next or waste space between, and other refinements of the adjustment, could hardly be explained without a precise scale drawing. Indeed, an inspection of the device itself (which the writer has had the privilege of seeing) can be satisfactorily made only with the more powerful type of hand-magnifier. Every adjustment of the tiny pieces must be correct

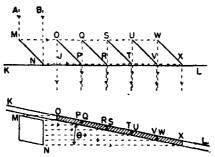

Figure 2: Drawings by Prof. Bowen, from a technical article in The Astrophysical Journal (Vol. 88, No. 2), plan below, elevation above. AB represents a cylinder of tays. Regarding these drawings Prof. Bowen there states: "In this diagram the beam of light is assumed to come from a lens of large focal ratio and, consequently, to approximate a cylinder of uniform crosssection, equal to that of the image. in the immediate neighborhood of the focus. This beam, bounded by the rays AM and BN, is intercepted just before it reaches its focus by the 45-degree mirror MN, which is placed near one end and slightly to the side of the spectrograph slit KL. This mirror is so adjusted that the reflected beam bounded by the 1ays MOQSUW and NPRTVX is parallel to the plane of the slit jaws and just grazes their surface. The mirror MN 19 rotated about the initial direction of the beam (AM or BN) into such a position that the reflected beam crosses over the slit AL, making a small angle with it'

to a ten-thousandth of an inch, and the technical skill required for its construction is hardly less admirable than the ingenuity of its design.

When the star's light has thus been put through the slit there is more to do, for the effective source of the light entering the spectroscope makes up in length what it lacks in breadth, and has the same area as before. With no alteration in the optical system of the spectrograph, the spectrum formed upon the plate will be much wider than before. The spectral lines will be longer, but no more intense at any given point on their length, so that there would be little saving in exposure-time. This main purpose of the instrument is attained by placing a plano-convex cylindrical lens just in front of the plate. This lens runs lengthwise of the spectrum, and compresses the image greatly at right angles to the

dispersion, and so makes the lines much shorter and more intense, without affecting their relative positions at all. Here again much attention has been given to the details of design. The great spectrograph of the 100-inch telescope is fitted with a battery of Schmidt cameras, which bring the spectrum to a focus not on a flat plate but along a curved surface. To satisfy the conditions just described the "cylindrical" lens must follow this curve on its outer surface, and be like a portion of a cylinder which has been bent along its length into a circular arc. To make such an affair out of glass would be very troublesome and costly; but some of the new water-white plastics were found to be admirably adapted for the purpose.

It may be permissible to report that these preliminary tests of the "image-slicer" in actual operation show that under rather ordinary observing conditions the exposure time may actually be reduced to a quarter of that which would otherwise have been necessary. Further details should be left to be announced by the observers.

The larger the telescope, the more trouble it collects from the air. Hence the image-slicer will probably be even more valuable as an accessory to the 200-inch telescope than with any existing instrument. Its usefulness is not confined to times of bad seeing For example, the image of a star low down in the sky is drawn out by refraction, no matter how good the seeing may be, and appears as a spectrum, with the red nearest the horizon, and the blue highest up. With an ordinary slit it is next to impossible to get the whole of this image in, and the observer must bear in mind what region of the spectrum he wants to get and guide on the colored image accordingly. But the image-slicer will take in the whole thing and solve this problem also.

FOR bodies which appear as luminous surfaces, such as nebulae, and perhaps a planet like Neptune, the new instrument will be of equal advantage. A great deal of work will still have to be done before its possibilities have been fully explored. But it is already evident that a major advance has been made in the detailed study of stellar spectra. With the new device, the 100-inch telescope should accomplish as much as the 200-inch could do without it.

It is particularly gratifying to record that this notable service to astronomy has been done by an investigator who has spent most of his time in problems of pure physics. It has been said, over and again, that co-operation between astronomers and workers in allied fields would be full of promise. This is a very fine instance of its successful results.—

Princeton University Observatory, November 5, 1938.

Everything Flows

NEW kind of scientist has come to the fore. He is studying almost everything that pertains to our existence, comfort, and enjoyment. He has gone so far as to give himself a new name—rheologist. As this word signifies, he is interested in the problem of the flow of materials. This subject has been studied intensively only in recent years.

We commonly think of gases and liquids as mobile and subject to flow, and of solids as rigid materials that do not deform, but before the critical eyes of the rheologist, everything flows! How rapidly the material deforms and how far depend upon the temperature and pressure to which it is subjected. The following examples and discussions of the flow occurring in stones, petroleum products, rubber, synthetic resins, and paint, suggest only a few of the rheological problems that are encountered in the preparation and use of materials with which we are familiar.

Traveling through the mountains and hills one becomes aware of the deformations that occurred in the rocks during the stupendous movements which took place in past ages. One sees places where molten rock has poured into fissures in colder stone. Rivers of lava have picked up bits of cooler rock and carried them along like twigs. The heat from the molten stone gradually softened the floating fragments, resulting in their elongation in the direction of flow.

Stones may also flow at atmospheric temperatures Such a phenomenon is well illustrated by a tombstone located in Rock Creek Cemetery at Washington, Industry is Finding Many Practical Applications of Science's Studies of the Flow Phenomena of Apparently Solid Matter as Well as of the Liquids

By R. N. TRAXLER, Ph.D.

D. C. This stone, which was mentioned in Scientific American many years ago (Feb. 21, 1903) was placed in a horizontal position in 1853 and originally supported by four short columns located at the corners During the 86 years that have elapsed since it was put in place, the marble slab has sagged without cracking, flow presumably occurred along the cleavage lines of the crystals of calcium carbonate composing the stone. The kind of deformation undergone by this stone is known as plastic flow and is distinguished by the fact that a definite amount of force, characteristic of the particular material, is necessary to initiate the movement. After this force or yield stress has been exceeded, the material flows like a simple liquid. In the case of the tombstone the weight of the marble, supported only at the corners, was sufficient to start the deformation and maintain it at a very slow rate until the caretaker inserted a fifth column at the center of the slab and arrested the movement

Professor E. C. Bingham has called attention to other examples of the molecular flow or slippage along crystal planes in stone at atmospheric temperature and under moderate pressures. In

the white marble veneering on the façade of St. Mark's Cathedral in Ven ice, the stone after centuries bulges out to the extent of several inches over a distance of about six feet without showing the presence of any cracks or fractures He also states that at the Palace of the Alhambra, in Granada, Spain, one of the two doors which has been christened "La Mezquita" exhibits an ancient facing of three slabs of marble The building has subsided, causing a considerable thrust upon the marble facing but the stone, "instead of break ing or of rupturing its casings, has simply bent and curved as if it were wood."

'N the great petroleum industry flow L is a subject of paramount practical importance. Removal of crude oil from the earth, its frequent transportation to the refinery through hundreds of miles of pipe, its passage through the involved processes that create a multitude of useful products, and finally most of the uses and applications of petroleum products, present unusual and interesting problems to the rheologist. The ideal lubricant for your auto or airplane motor should be sufficiently mobile at low temperatures to lubricate and protect the moving parts of a cold engine without becoming so thin and fluid at elevated temperatures as to lose all usefulness as a protection for the moving parts of the engine. Present-day lubricants are being tailored to fit the specifications laid down by the rheologist. The flow characteristics of heavy oils and greases change with temperature. As the molecular activity of such materials is reduced by decreasing temperature they often cease behaving like water and other simple liquids and become plastic in nature. This complication of the flow characteristics is due probably to the development of an internal structure through orientation or arrangement of the molecules present. These orientations are definite enough to result in alterations of the way in which the material is deformed by an applied force but in most cases do not proceed to the point of causing the appearance of crystals.

The sagging James Martin tombstone in Rock Creek Cemetery, Washington, D. C. The string and cigarette case show the extent of the sag caused by the flow of the stone (The notch in center of stone is due to ruin water ecosion and is not, as it may seem, a crack or break.)

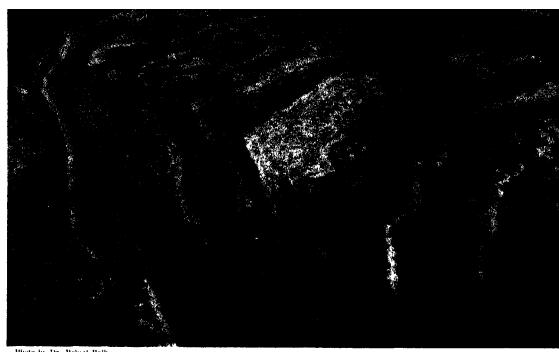

The low temperatures at which these unusual and anomalous flow characteristics appear are frequently encountered during the winter months. Any alteration in the structure of the oil or grease which removes those properties detrimental to its lubricating value offers substantial economic return to the user, because of greater protection to his machines.

Asphalt, which is obtained from the distillation of certain kinds of petroleum or is dug from naturally-occurring deposits, is used in many places because of its unique rheological properties. Recently, engineers of the Mississippi River Commission tried a new type of revetment for the protection of the river levees.

above New Orleans A mattress composed of asphalt, mineral dust, and sand, and containing wire reinforcement, was prepared on a barge from which it was fed into the water over a large roller. One end of the blanket was fastened to the inside of the levee but above the normal flood water line, the other extending to the bed of the river Thus, the inner surface of the levee and a portion of the bed of the river is covered with a flexible, elastic blanket which resists the scouring, crosive action of the strong currents of soil-laden liver water Sudden shocks will not rupture this type of mattress because of the strength imparted by the reinforcement and the clasticity of the asphaltic mixture. An elastic material will deform under an applied force but returns to its original position after removal of that force.

QUARTER of a century ago an A auto tire gave 3000 to 5000 miles of service. Now we like to boast of the 20,000 or even 30,000 miles we have driven at high speeds on a particular set of tires. In order to bring about this improvement the rubber is blended or compounded with various chemicals that confer greater mechanical strength combined with the retention of flexibility and elasticity for long periods of time The rubber is worked and kneaded between great rollers. During this calendering considerable heat is developed, the added ingredients are thoroughly dispersed, and the flow properties of the rubber are greatly altered. It has been discovered that the properties of a sheet of calendered, plasticized rubber are different in the direction of calendering than at right angles to that direction. This unique behavior has been taken as an indication of the presence and orientation of long molecules or aggregates of molecules known as micelles.

An example of flow folding in marble. This stone was not in a molten condition when it folded into the sinuous shapes shown here. Pressure and, especially, time are quite well able to account for this result

Various theories have been proposed to account for the great elasticity of rubber. One interesting view is that in any highly clastic material the molecules or groups of them are arranged much like a mass of coiled wire springs. A push or pull on the material compresses or extends these long molecules or molecular aggregates and when the applied force is removed the "coils" return to essentially their original position. The elastic properties of rubber can be reduced or destroyed by heat or excessive working, and may be lost if the material is maintained in a stretched condition for a long period of time. This last phenomenon is illustrated by the behavior of a rubber band which is left undisturbed about a bundle of papers for a considerable time. The rubber no longer possesses either elasticity or mechanical strength, the little coils appear to have become brittle and to have lost their ability to return to their original posi-

Since the day that Dr. Backland perfected the first commercially useful synthetic resin from formaldehyde and phenol (carbolic acid) the applications of these materials in our complicated, industrialized civilization have become too numerous to list Drinking cups, ash trays, telephones, dental plates, beautifully colored walls and cabinets, are a few examples of the many useful articles formed from synthetic resins, called by one theologist "organic glasses." The desired object is fabricated by placing a powdered resin mixture in a hot mold and applying pressure. Under such conditions the resin particles melt together and flow into a single mass which takes the form of the mold. During the molding operation the nature and properties of the material may or may not

In general, there are two types of syn-

thetic resin in use today, which are differentiated by their rheological characteristics: the kind that takes a permanent set during the molding operation and cannot be softened again at elevated temperatures, and the so-called thermoplastics that are rigid at ordinary temperatures but soften as the temperature is raised

ONTROL of the consistency (re-Sistance to flow) of the synthetic resins during their formation is very important. The reactions between the constituent raw materials, which are usually considered to be polymerizations and condensations (intermolecular combinations which will continue indefinitely unless halted by a drop in temperature or by chemical means), must be stopped at the proper point if the finished article is to possess satisfactory properties. Great ingenuity has been displayed in devising instruments for measuring rapidly and accurately the progress of these reactions as indicated by the changes in the fluidity of the product. The flow properties of the finished resins vary from the characteristics of simple fluids to those of plastics possessing distinct elastic effects. Elasticity becomes the dominant property in the synthetic rubbers In discussing these substances one authority has said ". . . and perhaps in many cases it is only a question of definition whether a substance must be considered as a resin or as a rubber." It is interesting that some kinds of resins show great flexibility (a bar or sheet of them can be bent around a sharp edge without cracking) but do not possess the ability to snap back into position after being deformed. The materials showing these unique and useful properties have been considered by certain investigators as existing in a gel (jelly-like) state, the lattice-work structure containing a

Flow in molten rock. The black mass at the left, and radiating lines, are obsidian
(volcanic glass) which flowed into cracks formed in the lighter-colored stone

relatively high content of a very viscous liquid, which prevents an elastic return after deformation.

When a finely divided solid is suspended or dispersed in a liquid the mixture frequently possesses unusual rheological properties. House paints are excellent examples of such mixtures. The same distinctive flow properties frequently appear when a liquid (for example, an oil) is dispersed in another liquid (water, for example) with which it is not miscible. Mayonnaise is such a suspension or emulsion. Even a catalogue of the present-day applications of dispersions, suspensions and emulsions, ranging as it would through cosmetics, foods, drugs, dyes, leather and photography, would require considerable space. The suitability and usefulness of these materials for their intended purpose depend to a great extent upon their flow characteristics, and consequently in recent years a vast amount of research has gone into the development of new methods of measuring the various rheological properties. We are now beginning to understand how these properties are affected by different variables: the particle size, size distribution, shape, and amount of the dispersed material present have been found to have a profound influence on the characteristics of the mixtures Of course the viscosity of the liquid employed is important and in certain cases chemical reactions occurring between the dispersed material and the suspending liquid also have a pronounced effect. Since these chemical reactions can occur only at the surface of the dispersed material, their effects will be most apparent when the particles or droplets are small (thus presenting a large surface area per unit weight or volume).

Some heavy, slow-moving dispersions

or suspensions become fluid when they are stirred, again returning to their original high consistency after standing for some time. Such mixtures are said to be thixotropic. With the passage of time orientation of the particles probably occurs, producing a structure in the mass which can be destroyed, at least partially, by mechanical agitation. Then, when the agitation is stopped, orientation begins to develop again with consequent increased resistance to flow or deformation. Another explanation, but the reverse of the above, has also been proposed in order to explain the phenomenon of thixotropy. It has been suggested that at rest the rod- or needle-like particles are in an unoriented arrangement, like a log jam in a river. The interlocking of the dispersed particles accounts for the resistance to flow shown by the mixture. When, however, the mixture is stirred the particles arrange themselves parallel to the direction of movement, like logs floating down a stream, and the mixture possesses greater fluidity. The difficulty with this explanation is that thixotropy also has been found to occur in suspensions of spherical bodies which cannot arrange themselves like logs They can, however, orient themselves to form a structural framework which can be broken down by mechanical agitation (stirring).

Many of the paints and lacquers in use years ago were difficult to apply because the brush marks would not disappear. Thanks to the rheologist, the objectionable property of poor brushability, which is chiefly due to the presence of thixotropy in the paint or lacquer, has been to a great extent eliminated. For many years little progress was made in devising new paints and protective coatings, or in improving those already

in use. Then, immediately following the World War, a new era in paint chemistry was ushered in by the appearance of the lacquers derived from a compound of cotton and nitric acid, and known as nitro-cellulose. The synthetic resins mentioned above have also been developed into very useful varnishes.

With the advent of the quick-drying cellulose and synthetic resin paints there appeared numerous problems for the student of flow. A finish which has been sprayed or brushed on a vertical surface must not flow under its own weight, but small irregularities and brush marks must disappear before the finish dries Such conditions demand a fine balance in the flow characteristics possessed by the paint. As an illustration of the success attending the work of the modern varnish chemist, is the fact that synthetic resin finishes are now used on airplanes and, although they are dry and hard in a few minutes, they present a perfectly smooth surface.

ANYONE who has walked on the wet sand of the beach has noted that often the moist sand suddenly becomes dry around his foot, but the sand immediately appears wet when the weight is removed. This phenomenon is known among rheologists as dilatancy and is dependent upon the almost unbelievable fact that pressure applied to a packed granular solid causes the mass to expand in volume, thus creating larger spaces between the particles. In the case of the beach sand the moisture on the surface which made the sand appear wet was drawn by the forces of capillarity into the larger interstices between the grains created when weight was applied to the packed granular mass. When the foot was raised the sand particles drew back together and the excess water was squeezed out of the smaller interstices between the grains and back to the surface. Dilatancy has an important bearing on the design of foundations, dams, or any structure composed of compacted granular materials. Incidentally, if the housewife wishes to get the maximum amount of ground coffee into a can she should not press it down but should shake or tap the filled container.

As we look into the future we can visualize rheology playing an increasingly greater part in the solution of the problems affecting man's comfort, convenience, and well-being. We see his transportation on sea, land, and air being made more comfortable and safe; we recognize the creation of more nourishing, attractive, and palatable foods; we find rheology marching side by side with the other sciences to fight a successful battle against diseases which have affected humanity since the beginning of our records. We see every human activity influenced by the work of the rheologist because—everything flows!

Mineral Waste Reduced*

be impossible, like perpetual motion, but industry manages year after year to get more without spending more. Forward-looking scientists and engineers still deplore the inefficient use of materials, mechanical energy, and man-power, but even a brief glance backward reveals that progress is being made, and quite rapidly.

Nowhere is waste more deplorable than in the production and use of minerals. Our supplies of mineral raw materials cannot be renewed; there is no possibility of getting a new crop. It took nature millions of years to segregate deposits that man can consume in a very short time. Few individual mines have an active life of more than a decade or two, and some of our useful minerals, provided we keep on consuming them at the present rate, may become as extinct as the dodo, for all practical purposes, within the brief span of one man's lifetime. Owing to the fast-increasing dependence of our civilization upon mincral raw materials, the idea that we are likely to rob future generations of their birthright commands the interest of government bureaus in conservation. Industry can scarcely be expected to take the same lofty interest in posterity-and it is debatable whether a miserly curtailment of useful consumption would be in the public interest even in the long run-but industry as well as Government has a stake in increasing the marginal utility of the minerals that it requires and in getting them more economically.

THAT better technology permits extracting more values from a given mineral deposit and thus enlarges our reserves of usable minerals is abundantly proved by the fact that waste dumps, tailings, and slag piles from the mining and treatment operations of fairly recent years are already being worked over, and sometimes re-worked again, as new methods make possible better commercial recoveries of the values. The implications of such developments upon the mining industries and upon the self-sufficiency of the Nation, however, are better revealed by reviewing the changes that have taken place during a definite period.

A quarter century ago, the Bureau of Mines published a thought-provoking little bulletin (No. 47), entitled "Notes

Froth flotation tests in the Bureau of Mines Laboratories. Research is continually under way in these laboratories to increase the recovered values of minerals

Conservation Progress . . . Agriculture, Industry Benefit . . . Miners Profit by Former Wastes . . . Greater National Security in Strategic Minerals

By PAUL M. TYLER

Chief Engineer, Nonmetal Economics Division, Bureau of Mines, Washington, D. C

on Mineral Wastes." In this bulletin, Dr. C. L. Parsons, the Bureau's chief chemist at the time, outlined certain opportunities for conserving mineral raw materials and, more important, expanding their economic utility. This summary affords a convenient backsight from which we can check up a few of the predictions then made and review the actual changes that have occurred during the intervening years.

Modern scientific agriculture is based upon the mineral industries in much the same way as the industrial and social accomplishments of the present-day machine age are predicated upon ample-supplies of mineral fuels and metals. A great number of chemical elements are requisite to the growth of the plants

that provide our foods and fibers, and three of them—phosphorus, nitrogen, and potassium—are exhausted from the soil so rapidly that they need to be replaced artificially and regularly through the medium of fertilizers.

In 1912, the United States—in fact, the entire world—had to go to Germany for its potash. To escape this complete dependence, efforts were being made to unlock potash from feldspar, leucite, alunite, and other rocks, and from seaweed. The fact had just been discovered that potash also was present in the brines of Searles Lake, California. All these sources were tapped during the World War emergency, but more prophetic yet was Doctor Parsons' remark, after describing the German

*Published by permission of the Director, U. S. Bucasa of Mines.

deposits of soluble potash: "No like deposits are known in this country, although if a large number of widely separated bore holes could be sunk in selected areas it is by no means improbable that beds would be found." Many years later, the Bureau of Mines and Geological Survey undertook a drilling campaign and now we have found that virtually inexhaustible supplies of potash, some of it very high grade, extend in non-outcropping beds beneath a wide area in New Mexico and Texas. Commercial production began in 1931.

We still buy potash from abroad, much of it still from Germany, but new discoveries have been made in other countries, as in the United States, and no longer must we pay four times as much as it costs to lay it down on our shores. If we chose, we could promptly

produce more than we are likely to consume.

Nitrogen, needful for munitions and industrial purposes as well as for agriculture, likewise was supplied by a foreign monopoly. During the World War, a possible blockade of the ocean lanes to Chile, if long maintained, would have precipitated a crisis that might easily have turned the balance in favor of Germany, which had already developed the nucleus of an industry for capturing nitrogen from the air. Whereas in 1913, the world drew nearly 56 percent of its nitrogen from Chile, 37 percent from coal, and only 7 percent from the air; by 1934, almost 75 percent came from the air, and 18 percent from coal, while only 7 percent was furnished by Chilean sodium nitrate. Production grew, meanwhile, from 851,400 to 2,108,500 tons

THE third principal plant food, phosphorus, was plentiful in the United States even in 1912, but received attention at that time because Florida miners were throwing away two or three times as much as they saved These appalling losses now have been largely reduced; the introduction of flotation and the allied art of oiling-and-tabling doubled at one stroke the possible economic recovery from current production, permitted old tailing ponds to be re-worked profitably, and expanded the already large reserves of commercial phosphate rock.

Phosphorus is a vital element in animal and human nutrition as well as an important plant food. Unless we replace it in our heavily-cropped soils, not only will the nation be threatened with decreased crop yields and higher prices for foods and fibers but the health of our animals and even that of our people

The microscope assists the Bureau of Mines principal mineralogist in his identification of mineral specimens for the purpose of advising producers as to their commercial uses

may suffer tragic damage. Last spring concern over our supplies reached fever heat. However, a Congressional Committee appointed to investigate has been deluged with data that dispel doubts as to our huge reserves; the latest news smoked out by the investigation is the probable existence of billions of tons in bedrock beneath Florida land-pebble deposits—but that is another story

Sulfur is another mineral that was being exported a quarter century ago, since it was produced more cheaply in Louisiana and Texas than anywhere else in the world; but we were also importing for its sulfur content nearly \$3,-000,000 worth of Spanish pyrite, mostly for making sulfuric acid for fertilizer manufacture Even then, about one fourth of our acid was made at copper and zinc smelters, but, in the far west, metallurgical stacks were belching out enough sulfur dioxide to make three times the quantity of acid then used in the entire country. Inasmuch as many of our smelting plants are in relatively sparsely settled regions, it is still more economical to make acid from sulfur or pyrite near the point of consumption; but significant progress can be recorded in salvaging the waste sulfur gases, largely through integrating and expanding the activities of the smelting works themselves.

The harmless disposal of noxious fumes has become more of a problem than it was 25 years ago, and unless the recovered acid can be utilized nearby for making some useful product that can be used locally or is valuable enough to stand the cost of shipping it elsewhere, the conversion of sulfur dioxide into sulfuric acid creates a worse nuisance than the gas itself. Now, however, the metallurgist has a new bag of tricks that

enables him to recover the sulfur in elemental form.

In the ceramic industries, great strides have been made in the substitution of domestic for foreign materials and in the betterment of materials. The adherence of potters to rule-of-thumb methods and their reluctance to try a new ingredient in their batch could not be dispelled so long as differences in the practical working properties of materials from different mines, especially clays, could not be explained convincingly by ceramic chemists. Some of these mysteries are being cleared up. The Bureau of Mines, in co-operation with other agencies, is working toward the duplication of the highest-grade kaolins by beneficiating (or processing) relatively impure clays. Improved technique, including the application of froth flotation, affords the means for fractionating and re-combining these components in uniform and reproducible proportions. A potter who hitherto dared use only a kaolin from a single locality in Czechoslovakia or a designated brand of Cornish ball clay can soon obtain a synthetic clay that will not only work the same way but may be more uniform in quality.

THROUGHOUT the gamut of ceramic industries—porcelain, enamels, stoneware, tile, glass, refractory products, and even common brick—the touch of science and the insistence upon everbetter products has called for better and better raw materials; this demand has been met not by exotic materials from far-away lands but by beneficiating those that lie at our own back door.

In addition to its use in pottery, highgrade clay is employed even more extensively in paper and increasingly also in rubber and other industries. American clays formerly were deemed unfit for such purposes but now, thanks to proper preparation at the mines, arc often preferred and generally are used instead of foreign clays except in a few localities where the hard facts of geography coupled with the advantages of water-borne transport make them over ly expensive. That such processing pays is indicated by the fact that a certain domestic clay sells as high as \$60 a ton, displacing not only imported clays but also costly satin white for coating the finest paper. Bleaching clays are now exported from the United States in fairly large quantities, whereas in 1912, despite a duty, imports of English fullers' earth were increasing steadily

Typical of former waste products for which new uses have been found is aisonic. Formerly 25,000 tons a year of this poisonous element were discharged

where it is mined for its own sake and not as a by-product. Leading its many uses is the surfacing of roll roofing, now grown into a large industry indeed; present signs portend plainly a tremendous expansion in consumption of ground mica in the paint industry. Long ago we exhausted the current supply of waste from mica mining and factory scrap, and after absorbing by-product flake from clay washing, we have taken to mining schists to augment our supplies of ground mica.

Chemical plants that once worried over getting rid of their calcium chloride are now able to sell all they can make Widely used for dust laying, it is increasingly employed in the construction of stabilized roads, ice control on highways and sidewalks, dust-proofing coal and other materials, refrigeration, and sundry other industrial uses.

New uses for bromine were sought

Developing a practical separation of numerals in a magnetic machine. Such research has resulted in large gams in conservation of our numeral resources

into the atmosphere by the copper and lead smelting plants of the United States, but most of this wastage has been stopped By cooling the stack gases, the arsenic fumes can be caught in bag houses or precipitated electrically. Now we use annually 35,000 tons of white arsenic, which has become one of our chief weapons in the far-flung warfare against insects and weeds. Over one half of this arsenic is imported from other countries in which it likewise is a byproduct and consequently can be recovered so cheaply that costs of transportation largely determine the price.

The utilization of so-called mica "waste" has progressed to the point

eagerly for many years, but after it came to be used in the production of Ethyl gasoline, supplies from by-product sources became so hopelessly inadequate that the Ethyl-Dow Chemical Company in 1934 began pumping raw sea-water in ever-increasing quantities simply to extract the bromine.

Bromne's sister element iodine, although seemingly destined always to be a Chilean monopoly, by virtue of its association with natural nitrates, likewise has altered its status during the quarter century under review. Research developed American supplies and means of recovering it from oil-well waste waters in California. We still import the element

from Chile but the price has tumbled from \$4 to 81 cents a pound.

Natural graphite continues to be imported, thwarting several attempts to draw economically upon our large domestic reserves, but to offset this we are substituting manufactured graphite, artificially made from anthracite or coke, for important uses; and by modifying our foundry and fine steel making practices, we no longer depend upon certain qualities of foreign graphite that formerly were deemed essential During the World War, we were tremendously concerned as to our ability to bring graphite halfway around the world from Ceylon and Madagascar to supply our munitions plants, but graphite has ceased to be listed among the strategic minerals

Fluorspar, barite, and asbestos are industrial minerals that we keep on importing in substantial amounts, but by progressively reducing mining waste and perfecting methods of treatment, our dependence upon foreign supplies has become less and less

AMONG non-metallic mineral products, probably none has made more substantial progress than Portland cement, the annual production of which doubled some years ago its 80 million barrel mark first passed in 1912. Technologic advances in the manufacture and utilization of cement have paced the increase in output, but more important perhaps is the benefit upon other industries. Largely in consequence of the increased use of cement, the production of sand and gravel has trebled in volume, a tremendous growth has occurred in the use of crushed stone, and great quantities of otherwise worthless slag are finding a profitable outlet as aggregates for mixing with cement to make concrete To show the inter relationship of industries it may be well likewise to note that all these industries owe much of their growth to the demand for good roads created by the automobile and conversely that the number of automobiles and sales of gasoline wherewith to run them would never have expanded to their present proportions had we been unable to use these materials for making good roads cheaply.

The foregoing examples cover only the industrial minerals discussed in the analysis and forecast made by the Bureau of Mines 25 years ago. There is no need to recite similar developments in the equally broad field of metals. Enough has been said to show that progress, remarkable progress, has been made toward eliminating waste, that minerals generally can be won more economically than ever before, that consequently they cost less in terms of human effort and less in comparison with other commodities, and that our country has grown more nearly independent of foreign supplies of minerals.

TALES THE BULLET TELLS

THE value of the scientific examination of firearms evidence is well known to law enforcement officers and an ever increasing use is being made of such evidence both in the investigation and prosecution of criminal cases.

The section of the Technical Laboratory of the Federal Bureau of Investigation which is devoted to firearms identification has had a very rapid growth. Over 560 cases requiring technical study of firearms evidence were examined during the year 1937 This is an increase of nearly 400 percent over the number of cases received during the year 1934. Cases were received from every state in the Union. Over 40 percent were submitted by state and local law enforcement agencies. In many cases, a firearms examiner from the Technical Laboratory was called to appear in court to testify regarding his findings, and there has not been a single instance in which the firearms testimony has been successfully refuted. The services of an FBI firearms examiner as an expert witness are furnished as a matter of co-operation without charge to law enforcement agencies in criminal prosecutions.

The FBI Technical Laboratory is equipped to handle many different types of firearms examinations. A most common type of examination is that in which test bullets from the gun of a subject are compared with those found at the scene of a crime Such examinations are very often made with prosecution of a certain suspect being dependent upon the results of the examination. In such cases, if an identification is effected, enlarged charts are prepared in the Laboratory to illustrate the firearms identification so it can be explained more easily to the Jury.

Law enforcement agencies are more than ever before utilizing the FBI Technical Laboratory for firearms examina-

FBI Experts Co-operate with Local Officers . . . Apply Laboratory Science to Study of Evidence . . . Give Full Reports . . . Attend Local Trials

By J. EDGAR HOOVER
Director, Federal Bureau of Investigation

tions as an aid to their investigation of a crime, even though no suspect is in custody. The investigation can be matetially assisted if, from the examination of an evidence bullet, the caliber and type can be ascertained. As an aid to such comparisons, the FBI Technical Laboratory maintains a reference collection of standard ammunition specimens.

The firearms section of the Technical Laboratory also maintains a file of rifling specifications of the principal types of weapons manufactured in the United States and foreign countries. This file is of particular assistance in enabling the examiner to determine the type and make of gun from which the evidence bullet or shell was fired Exact measurements of the rifling marks on the evidence bullet can be secured if the bullet is not badly deformed. These measurements can then be compared with the rifling specifications and very often the type of gun from which the bullet was fired can be ascertained. This information can be of great value to the investigation of a case in apprising the investigating officers that particular attention should be paid to a suspect in possession of that type of weapon.

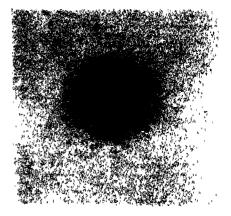

THE Technical Laboratory also maintains a reference collection of firearms which now numbers over 400 specimens. This collection offers valuable assistance for comparison purposes where unusual types of weapons are submitted for examination.

Examinations may be made with a view of determining the exact powder residue pattern appearing on clothing. Frequently, clothing of a person who has been shot is submitted to the Laboratory along with a weapon belonging to a suspect who admits the shooting but claims it was done under conditions of self-defense and at a certain distance from the murdered person. First, the

Test shots to show powder "tattooing" on cloth. Left: Muzzle of tested gun at six inches distance; and, right, three inches. (About half size) powder residue pattern, if any, around the entrance hole of the bullet in the victim's clothing is determined. Then, shots are fired with the suspected weapon through material similar to the clothing of the victim and the powder residue pattern surrounding these test shots at various distances can be ascertained. In the event a powder residue pattern similar to that surrounding the entrance hole of the bullet in the victim's clothing can be obtained, the probable distance from which the original shot was fired by the suspect can be determined.

Various other examinations in connection with firearms can be performed. Tests to determine penetration and trajectories are often conducted when the results of such tests have a direct bearing on the crime in question.

It has been suggested that local law enforcement agencies submitting evidence for examination should observe and record all information relative to the condition and position of the gun and ammunition specimens when found, always keeping in mind the possibility of developing latent fingerprints of value on the gun and ammunition specimens. The gun as well as the bullets and shells recovered should be handled with extreme care in order that the microscopic marks of identification thereon will not be distorted or obliterated. Great care should be exercised in packing the specimens for shipment and each specimen should be marked by the investigator in

order that the specimen can be identified, if necessary, in court.

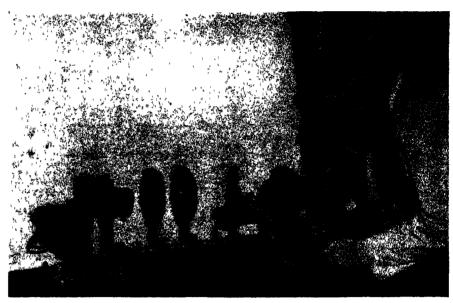

Whenever there are found marks caused by the explosive, they are examined to determine, if possible, the kind of powder used. By an examination under the microscope, the difference between smokeless and black powders may sometimes be determined. The grains of black powder appear to resemble coal in shape and are black or brownishblack. The grains of smokeless powders are made in particular shapes which enable them to be identified by use of the microscope. Many of them are formed into tubes, like spaghetti, or ribbons, which are then sliced to make the powder. Smokeless powders are usually entirely consumed by the explosion, whereas black powder usually leaves a residue.

The distribution pattern of burned and unburned powder around the hole made by the entrance of a bullet is useful in estimating the distance of the weapon from the object. If practically no "tattooing," as this is called, appears around the entrance hole, it is assumed that the weapon was held more than two or three feet from the object. The amount of spreading of the powder marks from the entrance hole indicates. with reasonable accuracy, the distance at which was held a weapon fired at less than two feet. That is, these distances vary for the different calibers, powder charges, lengths of barrels, and amounts of wear. When it is ascertained what kind of ammunition was used in a particular case, and the weapon is found, then by using the same ammunition, tests may be made through which it may be estimated at what distance the weapon was held to cause "tattooing" simılar to that observed.

BY chemical analysis also, the nature of the powder may be determined. In this connection, the fact that the powder contains nitrates or nitrites enables a very sensitive chemical test to be used. A solution composed of diphenylamine and concentrated sulfuric acid applied to the powder marks indicates the presence of nitrates or nitrites by an intensely blue color. This test is sometimes useful in determining whether a death is a suicide or a murder, by indicating the presence of burned powder on the hand, from which it is "lifted" by paraffin.

As an example of FBI co-operation with local peace officers, consider this recent case. On January 3, 1938, Everett B. Hughes of Pueblo, Colorado, shot and killed his wife. He was subsequently arrested and confessed the shooting but strongly maintained that he had acted in self-defense.

Hughes presented the following version of the crime—a version which was difficult to controvert because there were no eye-witnesses to the shooting:

An "evidence" bullet is clamped under one objective of the comparison microscope, a test bullet under the other. Adjustments bring markings into juxtaposition

His wife, the victim, hated him and had threatened to leave him in favor of another man. On the night of the killing she had become particularly belligerent and had seized a revolver and had started advancing toward him, giving every indication that she intended to kill him then and there. He had no chance to escape, and being in fear of immediate death, he had seized a .22 rifle standing nearby and had fired a shot which passed through her head and caused her immediate death. He was then extremely frightened and took the victim's body to a spot in the country nearby where he buried it in a shallow grave

Hughes claimed that the burial was not occasioned by a feeling of guilt but was merely the natural consequences of his fright.

The Sheriff's Office at Pueblo, Colorado, believed that this was a cleverly planned and deliberate murder and intensive investigation was launched into the circumstances surrounding it.

It was found that Hughes had, a few days before the murder, secured from the victim a number of sheets of paper bearing her signature on the bottom. He had secured this writing under pretext, advising his wife that they were to be used to write verses on in connection with festivities in the Hughes home on New Year's Eve. Hughes had written a few verses on these slips of paper, but he had kept some and had written typewritten letters to his son and daughter over the victim's signature, which stated that the victim hated him and was soon to leave him. He had even typed a letter to himself which contained a similar message. These circumstances indicated that Hughes had been planning the murder of his wife for some time.

Examination at the scene of the crime indicated to the investigating officers that the murder had been brutally and quickly executed. Although Hughes

maintained that his wife had been shot while moving toward him in one part of the house, a chair, in another part of the house, contained stains that resembled blood. It appeared that Hughes had shot his wife while she was sitting in this chair unaware of danger.

The section of the chair containing stains, and the .22 caliber rifle belonging to Hughes, were transmitted to the Technical Laboratory of the FBI for extensive analysis and tests. Findings of the examiners were furnished to the Sheriff's Office at Pueblo, Colorado, and two of the examiners were present as witnesses when Hughes was tried for murder in March. The expert who made the examination of the chair testified that the chair contained stains of blood. This testimony nullified the statement of Hughes that the victim had been shot in another part of the house while moving toward him.

OTHER testimony was given by a firearms identification examiner from the laboratory to the effect that Hughes' gun had fired the shot which took the victim's life. Further testimony given by this examiner was of vital importance in attacking Hughes' version of the crime. As a result of tests conducted in the laboratory, he was able to state that the gun used in the murder would make a powder residue pattern similar to that which surrounded the victim's fatal wound only when held within less than one-half inch from the object through which the bullet passed. This absolutely contradicted Hughes' statement and gave valuable support to the State's contention that Hughes had held the gun almost in contact with the victim's head while she was sitting in the chair, possibly sleeping, and had then pulled the trigger. Hughes' story of shooting his wife while she was advancing toward him and still at some distance was thus discredited.

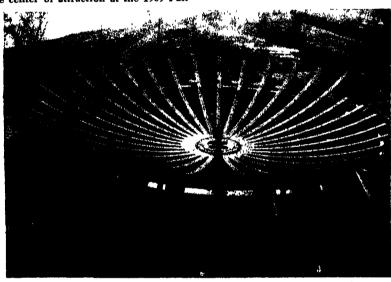

Dominating, even before completion, where they will be the center of attraction at the 1939 Fair

STEEL IN THE THEME

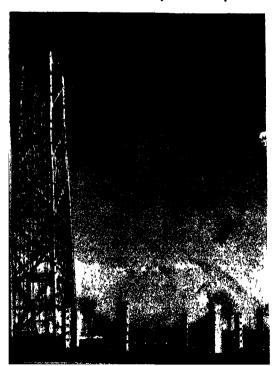

New York World's Fair Theme Center... Perisphere and Trylon... Design and Construction Presented Unusual Engineering Problems... Unique Structures

THE most unusual sight at the New York World's Fair of 1939 will never again be more than a memory. At least that is the opinion of those engineers, designers, and construction men who had a part in fabricating and erecting the steel for the Perisphere and Trylon, Theme Center of the Fair

Whoever said that "looks are deceiv-

Factory test-assembly to assure fit of lower part of the Perisphere. Below: The Trylon starts upward as Perisphere supports are erected

ing" might have had the Perisphere in mind. Externally, this huge sphere is indeed the essence of simplicity, but internally it is one of the most complex engineering jobs ever tackled and completed successfully.

The Trylon stands as a sentinel over the Theme Center's major structure. It will function during the Fair as a direction finder for traffic from all points of the compass. Traffic control in the Fair grounds proper will be guided from this tower. But from an engineering point of view, the Trylon follows customary practice in design and construction.

"Never in our many years of constructing bridges, buildings, and other steel structures in practically every country in the World and under all manner of weather and climatic conditions, have our engineers ever met with a problem more unique or interesting than the Perisphere," said L. A. Paddock, President, American Bridge Company, subsidiary of U. S. Steel Corporation.

Although the Perisphere will appear as a single globe when finished, it is actually a sphere within a sphere. In this structure, however, the two spheres do not have a common center. The inner sphere, which will contain huge revolving platforms, is raised a distance of three feet, although it will be attached firmly to the outer sphere by means of trusses to form a single shell. This type of construction was necessary in order to provide space for the heavy drum girders and other steel members which are required for the support of 9,000,000 pounds which the Perisphere will weigh when finished.

"In buildings of today, comparatively few of the structural steel members are curved, but in this Perisphere all pieces, except columns and center plates, will have curved or warped surfaces to fit the contour of the spheres, and it is these conditions which, in certain instances,

Large, assembled, curved girders are lifted into place and rivetted as the Perisphere begins to show its shape

gave our engineers mathematical head-aches," Mr. Paddock said.

In order to make absolutely sure that every piece would fit exactly as planned by the engineers, the main trusses were assembled and the field splices reamed while assembled in a jig at the Ambridge, Pennsylvania, plant, and then dismantled for shipment to the Fair site.

A huge ball such as the Perisphere, standing as high as an 18-story building, will present considerable resistance to the wind. This factor introduced one of the important problems. When finished, the Perisphere will be able to withstand a wind of 90 miles per hour. There is nothing alarming in this, however, for although a wind of this velocity produces a pressure of 30 pounds per square foot on the flat surface of a bridge truss, it produces a pressure of only 15 pounds per square foot on the surface of a sphere, as was determined in wind-tunnel tests. Therefore, there need be no fear that the Perisphere will blow off its pedestal and go bouncing across the meadows.

THE Trylon, which towers 700 feet high—taller than the Washington Monument—is unusual among tower structures because in the past they have generally been left open so that the structural steel is visible and so that they would offer a minimum of resistance to the wind. The covering on the Trylon made it necessary to introduce added strength in structural steel to overcome wind resistance, but even so, the top of the Trylon may sway through an appreciable arc as do all structures of great height.

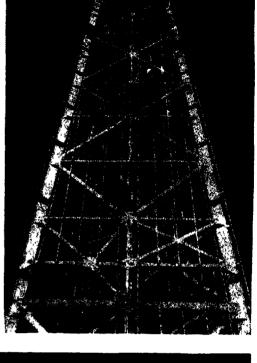

In order to support the extreme load of the finished Perisphere, including the thousands of people who will visit it hourly, the eight columns holding it up rest on mats of reinforced concrete 12 feet below the ground, and these mats are themselves in turn supported by 528 creosoted, 90-foot, wooden piles, driven down into the swampy soil.

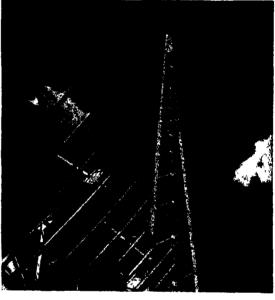

An idea of the size and weight of Perisphere structural steel may be gained from this photograph of rivetting operations under the huge sphere's curve near the base

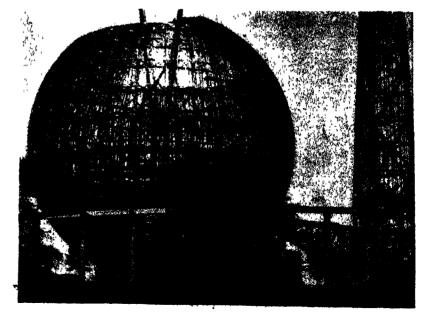

Right: Pointing high into the air, the Trylon steel receives the first of its covering, or outside wall, from the top down

A BILLION GALLONS A DAY

Left: One of the electric motor installations of the Colorado River Aqueduct pumping system, by means of which water will be delivered from the Colorado River through 242 miles of canals, tunnels, conduits, and siphons to Los Angeles

WHEN the Colorado River Aqueduct is completed a few years hence, 45 huge electric motors will drive pumps to lift 8,300,000,000 pounds of water daily and deliver it from the settling basin above Parker Dam to Southern California. The total height through which this water will be lifted is 1616 feet, to be accomplished in five steps, nine pumps working at each pumping plant. The pumps, set below water level to be self priming, will be connected to the motors through 40-foot-long steel shafts. Details of this engineering feat are shown in the accompanying photographs.—Andrew R. Boone.

Below: Since the pumps are connected to the motors through long shafts, the scroll cases of the pump units are accurately leveled by a plumb bob and a spirit level on horizontal beam

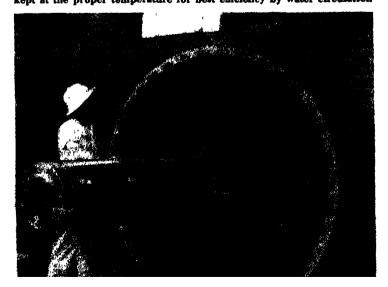

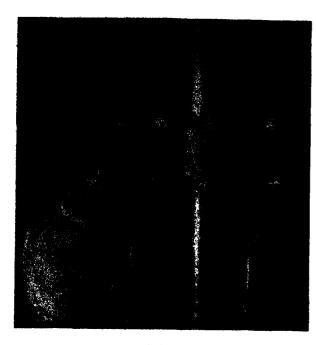

One of the scroll cases within which the impeller of one of the huge pumps will rotate. These cases, placed below water level, will be set in concrete. The impellers will throw water outward and force it upward through pipes

Below: Pump replacements and repairs will be difficult and expensive, so the greatest care is taken to insure proper running fit between bearing surfaces. Here two engineers are "miking up" one of the large bearing rings used in the pumps

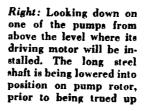

Below: The 35-ton rotor of one of the electric motors which are capable of developing 12,500 horsepower each. When these motors are in operation they will be cooled by air moving in a closed circuit and kept at the proper temperature for best efficiency by water circuittion

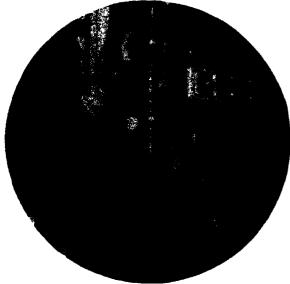

Left: Throughout the entire installation of the pumping equipment for the Aqueduct, the most modern testing instruments are in constant use to guard against imperfections. Here a technician is using an electrical micrometer to true up one of the motor shafts

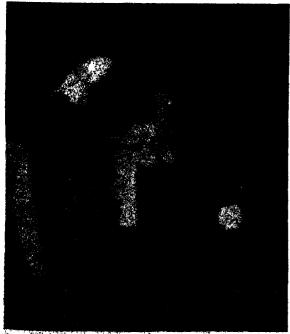

Large steel pipes used in the Aqueduct are X rayed to be sure that no flaws are present which might later develop disastrous leaks. A close-up view of the X-ray tube is shown in the circle at the left

A MONTHLY DIGEST

DANGER IN LOW VOLTAGE ELECTRIC SHOCK

LOW voltage shocks of even 12 volts can be dangerous, H. W. Arlin of the Westinghouse Electric and Manufacturing Company told a meeting of the Safety Congress

Despite the general belief among workmen that voltages up to 110 to 220 volts cannot produce fatal shock unless a man has a weak heart, Mr. Athn cited reports on tests conducted by various organizations which show that when an electrical circuit is completed through a wet contact, any voltage in excess of 12 volts is dangerous—Science Service.

NEW BUILDING MATERIAL

PY treating with lime the waste liquors from the picking of steel, a new type of building block having valuable properties is being produced. Steel mills have had difficulty in the past in disposing of the waste acid from the picking of steel since this cannot be dumped into streams. The preparation from this waste of a satisfactory building block is expected to convert this liability into an asset. The blocks, marketed under the trade name of Ferron, consist principally of calcium sulfate with an admixture of oxide of from They are light in weight and possess some advantages over customary gypsum blocks although they have a brown color.—D. H. K.

MICROSCOPE LENS: PLANACHROMAT

AN important forward step in lens-making and the end of a long period of research is marked by the announcement, from Carl Zeiss, of the Planachromat, a new microscope objective which gives equal sharpness in definition throughout the whole field of vision. Lenses just received from the laboratories in Jena are considered to be a definite improvement on microscope objectives available up to now

Heretofore the field of magnification could be made flat only at the cost of lessening definition at the center While the spot at the center of the field was sharply in focus, the field became increasingly blurred toward the edges. Scientists had to be satisfied with having the utmost clarity at the center of

Conducted by F. D. McHUGH

Contributing Editors ALEXANDER KLEMIN

the field at the expense of the surrounding area, rather than equalized but lessened definition

At present the new lenses are available in two magnifications, 9x and 40x, or the low and the medium members of the usual battery of dry lenses

SHOCK ABSORBER FOR STEEL

THE 190,000-pound flywheel shown in our illustration is being "faced" to a perfect circle in the East Pittsburgh works of the

Westinghouse Electric & Manufacturing Company before it goes to work as a cushion of power in a steel company's blooming mill Part of a 6000-kilowatt motor-generator unit built by Westinghouse for the steel concern, the flywheel will maintain the generator at a steady power output despite peaks and recessions in load requirements as steel billets are pressed between the mill rolls.

RIFLE SHELL FIRE ALARM

LONG-rifle shells of .22 caliber and made by Remington, primed, but with no lead bullet or powder charge, are now being used on airplanes in connection with a fire alarm system. The shells are mounted at strategic points about the engine, and from them tubes lead to the instrument panel Flame or heat of 250 degrees explodes a shell, flashes a signal, sounds an electrical

When the force of the explosion flicks the red signal light, the pilot releases, through distribution pipes, carbon dioxide gas which

This huge flywheel will absorb shocks in a steel mill

envelops the engine and snuffs out the fire.

The alarm system is valuable on planes with outboard motors on the wings where a flare in a motor housing could not easily be

This new device has also been constructed to operate an automatic fire-extinguisher, from which the carbon dioxide gas is released at the instant of the explosion.

Many American-built transport planes are equipped with this device. The Argentine Government recently purchased 100 planes for its army and navy, 60 of which are equipped with the Lux Fire Detector System, which is manufactured by Walter Kidde and Company.

SWEET SMELLS

A HUGE outlet for sweet smells is the cigarette industry. Although frankly perfumed cigarettes have only a small market, every widely used cigarette is flavored; that is, it contains some spice, extract, essential oil, or sugar that will modify the taste and odor of the tobacco. In 1929, for instance, a favorite was coumarin; one manufacturer found that maple sugar gave somewhat the same smell and used 4,000,000 pounds of it in a year.—Technology Review.

ONE-MAN SUBMARINE

ARLY rising residents of Michigan City on a recent Sunday morning gaped in astonishment at a strange object that was passing through the streets as they stepped out to gather in the morning milk. The contrivance looked for all the world like a huge speckled trout mounted on an automobile trailer—a trout with adenoids, for its mouth appeared to be open; a trout with two baleful-looking eyes, no fins and a queer kind of tail.

Some of the curious threw on a few clothes and set off in hot pursuit. Down at the water front they got a better look at the contraption which turned out to be a one-man submarine. It was about eleven feet long, three feet high, and about two feet through the middle.

According to Barney Connett, a garage mechanic by trade, the body was made of

Steel trusses, usually hidden from sight in ordinary building construction, will remain exposed in the "inside out" exhibit building of U. S. Steel at the New York World's Fair. Here is shown the skeleton taking shape, ready to support a stainless-steel dome 66 feet high and 132 feet in diameter. The shape of the building carries out the motif of the Fair's Theme Center which is described in some detail on page 24 and illustrated on the front cover of this number

steel and weighed just over a thousand pounds. The power plant, he said, consisted of five regular Kathanode automobile batteries, four of which furnished the power for the 38 mile crossing of Lake Michigan.

When everything was ready, Barney low ered himself into the cramped interior and pulled down the hatch cover which looked like an over-size pith helmet with a flag pole on it. The flag pole, of course, was Barney's periscope.

The little craft began moving silently out into the lake and Barney submerged until only the periscope was visible from shore. The inventor claims his sub will go to a depth of 31 feet, but you can't go down that far with a four-foot periscope—not and still see where you're going. So Barney stayed within about three feet of the surface Behind him came the *Idler*, a 65-foot sloop carrying two professional divers—just in case.

About eight miles out from Michigan City the under-water craft ran into a storm, but her batteries pushed the boat steadily through the rough water.

When the submarine purred into Navy Pier, Chicago, and Barney climbed out, the sub was still going strong, he said, but he was exhausted—and happy. He had done what he set out to do

FINGERPRINTING CHEMICAL COMPOUNDS

A-RAY diffraction patterns produced by crystalline compounds have long been used in chemical investigations. Full usefulness of these patterns, which are characteristic of the material investigated, has been impossible in the past because no sure method of indexing multitudes of patterns existed. Recently such a system has been devised by chemists at the Dow Chemical Company and applied to the patterns produced by a thousand different chemical compounds.

The one-man sub ready to be towed to the water, and, right, under its own power

This system of classification, which is capable of extension to other compounds, provides a method of identifying chemical compounds as sure and accurate as fingerprinting identifies persons.

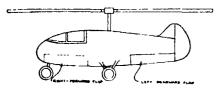

Diffraction patterns are made by placing a small specimen of powder of the unknown material in a narrow beam of X rays which are thereby refracted to make a record on a photographic film. This record consists of lines in different positions, characteristic of the arrangements of atoms in the material investigated. The important value of the method lies in the fact that it will detect and make a permanent record of the various materials present in a mixture without destroying the sample or otherwise affecting it—D. H K.

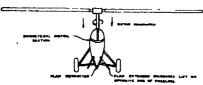

THE HELICOPTER TRIUMPHANT

At the Franklin Institute, under the auspices of the Philadelphia Chapter of the Institute of the Aeronautical Sciences, there was recently held the first meeting ever devoted exclusively to Rotary Aircraft Beginning with an introductory paper intended to give a comprehensive view of the entire art by the Aeronautical Editor of Scientific American, papers were delivered by almost all the outstanding exponents of the Autogiro, the Gyroplane, the Convertaplane, and the helicopter. Space will permit us to cover only the most significant features of this highly successful gathering

highly successful gathering

The honors of the meeting went to the helicopter W Laurence Le Page showed a film of the Focke Helicopter which we have described in these columns. The film was positively astounding. The machine per-

Side and front views of Hafner's rotor plane employing side flaps

formed the most marvelous evolutions inside a hall, flew forward at 75 miles an hour, backward at 18 miles an hour, hovered, turned around its own axis, all under perfect control That highly distinguished aeronautical engineer Grover Loening confirmed the astounding characteristics of the machine. On one occasion he stood beside Professor Focke, when an inexperienced pilot was in the cockpit Not knowing what to do, he brought his machine completely to rest some ten feet from the ground, and called out "Was Soll Ich Thun?"!

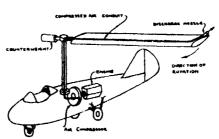

But although the Focke-Wulf helicopter has broken all records, and constitutes a remarkable achievement, the helicopter is still in the rapidly evolving stage and many other forms will doubtless present themselves.

As we had occasion to state previously,

it is highly desirable to have a helicopter with the lifting qualities and the simplicity of a single large lifting airscrew. But since the large airscrew turns slowly its reaction torque is high. This is how two excellent engineers propose to meet the reaction torque while using one rotor:

Raoul Hafner (of Hafner Gyroplane fame, a windmill type which has been most successful in England) is about to construct a craft in which a relatively small rotor will be used, turning rapidly so as to give efficiency in forward flight and a relatively small reaction torque. Combined with this Mr. Hafner will use a long, slender fuselage, provided with two side flaps front and rear. These flaps, displaced in the downwash of the rotor, will produce lateral forces, which will take up the reaction torque with a minimum of air drag. This ingenious idea was very well received.

Professor Montgomery Knight suggests a different plan. He will employ a single blad-

Knight's single-blade rotor plane

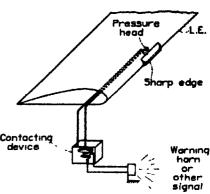

ed airscrew (suitably counterbalanced) and instead of using a mechanical transmission will supply compressed air to the tip of the blade. The air ejected from the blade will drive it around, so again reaction torque will be eliminated in a highly novel form of direct lift machine. This idea was subjected to many criticisms such as the difficulty of balancing a single rotor and the fact that another conversion of energy is introduced (instead of the efficient tilting forward of the rotor to produce propulsion) and a very inefficient one at that.

Indicative of the wide interest existing in this art is the fact that Edward Noble, chairman of the Civil Aeronautics Authority, addressed the gathering at a banquet which took place during the highly successful and interesting symposium.—A. K.

A STALL WARNING INDICATOR

THE "stalling" of an airplane wing, which occurs when the nose is raised too much, is highly undesirable, since it may lead to loss of control, falling off on one wing, and sometimes to an unpleasant spin. With stalling of the wing, the airspeed drops and in horizontal flight the airspeed meter is in itself a stall indicator. But in making a turn, the lift is greater than the weight of the airplane, because centrifugal forces have to be met, and the stalling speed is in turn higher than the stalling speed in ordinary, straight flying. Thus the airspeed meter becomes a very poor guide to safety in maneuvers.

To meet the difficulty the N.A.C.A. has developed a special stall indicator. Near the tip of the wing, close to the leading edge and just above its surface, there is placed a Pitot or pressure head. At the leading edge

Airplane stall indicator

of the wing, ahead of the Pitot, a sharp edge is fitted. With this introduction of the sharp edge, a local stall and loss of pressure at the Pitot tube occur well ahead of the general stall of the wing. When this local loss of pressure occurs, a contacting device automatically closes an electric circuit, and an electric horn in the cockpit gives a warning blast.

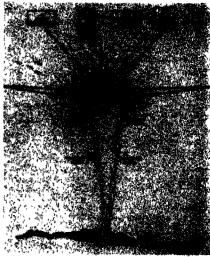

Full flight experiments at Langley Field, in a small Fairchild airplane, have shown that while this machine stalls at 42 miles an hour, the horn blows at 59 miles an hour The pilot thus receives a warning well ahead of the danger zone.

There are minor difficulties to overcome. The pressure tube must be heated to prevent ice formation, and the device must be so arranged as not to increase air drag—the perpetual enemy of the airplane constructor Nevertheless, it is clear that this ingenious and simple device is a valuable safety measure—A K

ABSOLUTE ALTIMETER AND COLLISION INDI-CATOR

IN our opinion the development and successful testing in a Boeing transport plane of an absolute altimeter and collison indicator is one of the epoch-making advances in aviation. The absolute altimeter was developed jointly by Bell Telephone Laboratories, Western Electric, and P. C. Sandretto, Superintendent of the Communications Laboratory of United Air Lines.

The basic principle of the device can be

Simplified diagram of operation of the newest radio absolute altimeter

simply stated. A short-wave radio signal 18 transmitted from the airplane to the earth. The signal is reflected back from the earth. the time elapsed in the reflection of the signal is measured, and this time is translated into a direct and accurate meter reading of the plane's altitude in feet. Due to the use of an ultra-high frequency the altimeter is entirely free from static interference. Despité any weather conditions, or irregularity of terrain, the pilot can read his height directly above the earth whether it is only a few feet or is thousands of feet. A warning signal can be incorporated in the apparatus. Also, the altimeter can be directed forward at any desired angle, serving then as a collision indicator against moun tains or other obstructions. The weight of the apparatus is only 40 pounds.

This sounds very simple, but our readers will agree that an enormous amount of research work must have gone into the invention

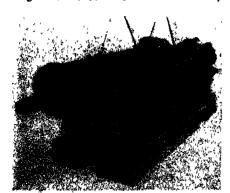

A really technical explanation is not yet available. No doubt it will find its way eventually into the technical journals. But the accompanying diagram will serve to give a general understanding of its functioning (See lower right drawing, opposite page.)

In this diagram, A is the radio transmitter operating on a frequency of 500 megacycles, the highest frequency ever used for practical purposes in short-wave radio The transmitter is connected to the transmitting antenna E only 12 inches long, located below the wing of the plane and about eight feet from its center This transmitting antenna sends a signal G to the ground J, not in the form of a pencil or beam of radio waves, but in a large hemispherical pattern. The ground J reflects this radio energy back to the plane where it is received by the receiving antenna F. The radio receiver D, connected to the antenna F, receives a wave K from both the transmitted wave and the reflected wave. The interference thus created is measured by the device C, and by suitable calibration the measuring meter gives a reading on the "Terrain Clearance Indicator" B.

We hope that the instrument proves just as satisfactory in actual service as it has in the laboratory and in the experimental flights.—A. K.

Unitwin Power Plant

DETAILS are now available of the Unitwin power plant in which two Menasco Buccaneer engines will be coupled to a single propeller in such fashion that when one engine fails the other will still keep the airscrew going. The advantages of such an arrangement are obvious. With the ordinary

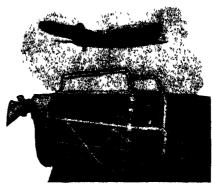

Unitwin

A mobile airport provides mechanical servicing facilities in the field

twin-engine power plant, with each engine mounted out on a wing, the failure of one engine sets up a turning moment which has to be rapidly counteracted by the pilot Also, long leads have to be provided from the pilot's cockpit to the engines. With the Unitwin, all the safeguards against failure of one engine are provided, yet the turning moment is completely eliminated. Flight on one engine is thus much more of a certainty

The Unitwin engine is shown in one of our photographs. Two six-cylinder, air-cooled, inverted engines are placed side by side, with the propeller shaft exactly between them. The two engines are geared together to the common propeller by means of an over-running clutch (which has been used in many lines of industry, as well as in

Installation of a Unitwin power plant in a low-wing Vega monoplane

free-wheeling and over-drive units in automobiles). When the engine on either side quits, the over-running clutch immediately brings it out of engagement. Each engine has a flywheel incorporated in the gearing unit in order to prevent the motor from stopping when idling.

Another of our photographs shows the installation of the new power system in the nose of the low-wing Vega monoplane, which is being rushed to completion by Vega Airplane Company, a subsidiary of Lockheed. The nest looking Vega will carry five or six passengers in all the comfort of the largest airliner and will be particularly useful on

feeder airlines. The Vega should also be very interesting to private plane owners seeking the maximum of twin-engine safety. With a useful load of 1729 pounds, and a gross weight of 5400 pounds, the new Vega will have a maximum speed of 210 miles per hour at 7500 feet altitude, and a cruising range of 600 miles—A. K.

A MOBILE AIRPORT

THE wars in Spain and China and the records of other military operations indicate that in air warfare the provision of a limited number of airports and landing fields may not be enough. It appears desirable to provide a mobile airport or flying base which can be set up anywhere, travel over almost any terrain, and provide ample facilities for the repair or maintenance of aircraft. Mr. K. W. Couse, of New Mexico, has in very logical and thoroughly engineering fashion developed a traveling or mobile airport which has been exceedingly well received by all the authorities who have examined it.

Mr. Couse has made no startling inventions or evolved intricate gadgets. He has merely used a high degree of common sense. A glance at the photograph of the mobile airport will indicate its general character. Here are its specific features and accomplishments:

With two driving rear axles, powerful gear reduction, and removable steel tractor treads, the Couse mobile airport can climb. continuously, up a grade of 35 percent. The wheel base is shorter than in standard truck designs, which makes for roadability and the ability to make very sharp turns. The short wheel base also allows an irregular road surface to be followed. The special design of the chassis brings the center of gravity down quite low, which means more steadiness on the road. As the Couse unit is specially designed to house heavy equipment and machinery, it can carry large weights without the over-all weight of the unit becoming excessive. The two spare wheels in front also serve as a fine bumper.

So much for the automotive side of the picture. From an aviation point of view

there are many desirable features. The neatly installed shop equipment includes a lathe convertible into a milling machine. welding equipment; other machine tools, a generator with ample capacity for operating the various tools, drill presses, hand tools, and so on-everything needed for field repair of aircraft. The sides of the vehicle swing out and up to provide shelter in inclement weather, with the addition of a tarpaulin at the end of the hinged roof. There is a crane and an engine workstand, as well as radio equipment for both transmitting and receiving A searchlight at the front of the vehicle can be made to indicate the direction of the wind There are also two other searchlights, so that three vertical beams can be set up to mark out the boundaries of an emergency field -- A K

IMPROVED STREAMLINED WHEELS

THANKS are due to the Army Air Corps for the accompanying photographs of a streamlined airplane wheel and tire with smooth contour. For a non-retractable chassis, the advantage of a streamlined wheel is

so obvious as to need no comment. To improve operation on soft ground the Air Corps engineers have widened the tire contour at the tip of the tread as the picture indicates. To reduce the opening in the wing with a retractable chassis, the designers are making the wheels smaller and smaller, and quite recently the standard 60-inch size (employed on large bombers) has been reduced to 56 inches diameter. For a craft weighing something like 70,000 pounds, the utinost efficiency and greatest reduction in size are absolutely essential.—A. K.

CIVIL AERONAUTICS AUTHORITY

POLICIES of the Civil Aeronautics Anthority are not yet clarified, but its members have made an impression of earnest good will and willingness to work hard. The addresses delivered by members of the Authority during National Air Travel Week were well informed, sensible, and to the point. In particular the remarks of the Chairman, Edward J. Noble, broadcast from Annapolis, Maryland, during Air Week,

brought out the progress in air transport in striking fashion. Mt. Noble compared air transport of ten years ago with that of today

Ten years ago, there was no information on the upper atmosphere. Now we talk about flying in the stratosphere and the substratosphere, in pressure cabins, and think nothing of it. Ten years ago there was little or nothing available in radio, instruments,

Above and left: Views of the improved streamlined airplane wheel

sound proofing, aviation medicine. Other contrasts are equally marked

Yet in a country of 130,000,000 people only 2,500,000 fly for any reason whatsoever. The airlines check in a million passengers a year, but they know that the same people are flying frequently and they actually get only a quarter of a million passengers.

Fear still remains. As fear is vanquished, further progress will be stupendous or colossal, or any other Hollywood adjective (iting the various well developed aids to navigation. Mr. Noble summarized the safety situation in the following words. It is 300 percent safer to fly now than in 1930. The airline ratio is one fatal accident to each twelve million miles of flying. At that rate you can fly around the world four hundred and eighty times before you need to be afraid of flying into it! That figure is absolutely correct and it is something for timid souls to think about "- A. K.

GLASSY LANDINGS

WRITING in Aero Insurance News Letter, Jerome Lederer states that judging height accurately when alighting on perfectly calm water is practically impossible. Within the last year, about 50 pilots and passengers have lost their lives in various parts of the world because of "glassy landings". Under glassy conditions, the pilot should not guess at height and follow the conventional maneuver of gliding down and then flattening out a few feet from the surface. He may flatten out too late, and nose into the water with possibly disastrous consequences. What he should carry out is a "power stall." At about 50 feet from the surface of the water,

he should open up the throttle of the engine a trifle, and pull the nose slightly above the horizon. The plane will then lose altitude slowly in an almost stalled attitude. The sub-sequent contact with the water will be harmless, although to land in a power stall on the much harder ground might not be so judicious.

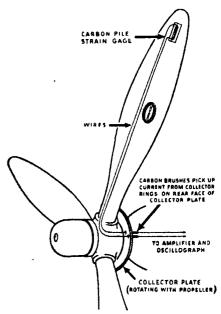

Incidentally Mr. Lederer argues that land airports should never be located on islands or terrain largely surrounded by water because of this same difficulty of judging height while still over the water and making the approach to the field -A K.

PROPELLER STRESSES MEASURED IN FLIGHT

IT is not the steady load which causes failure of a metal propeller, but vibratory stresses due to the uneven torque cycle of the engine or its dynamic unbalance. The reliability and safety of the propeller have therefore been increased by intensive study of its vibration. Hamilton Standard have advanced this study of propeller vibration to such a degree that in the 20,000 controllable pitch propellers built in recent years not a single failure at the hub has been reported, and the less serious blade tip failures are very few in number.

Now Hamilton Standard announces an ingenious and simple method of measuring the stress at any point of the propeller bladeduring flight, which should advance knowledge and hence safety still further

The device is illustrated diagrammatically in one of our drawings. It depends upon the phenomenon that certain materials in crease and decrease their electrical resist ance in direct proportion to the loads or

For measuring propeller stresses

stresses imposed upon them The resistor or strain gage used in this case consists of a "carbon-pile" strip approximately two inches long, a quarter of an inch wide, and one sixteenth of an inch thick. This carbon pile, cemented lengthwise to the propeller blade but insulated from it electrically, is attached at its ends to two fine wires which carry direct electrical current. As the propeller blade stretches under load, the resistor stretches with it, and increases in

electrical resistance so that the current flowing through the system varies. This varying current is used to operate an oscillograph which consists essentially of a coil between the poles of a magnet. The coil moves in the magnetic field, following the change of the electric current in the re sistor. A tiny mirror is mounted on the moving coil, and a fixed beam of light is focused upon the mirror As the coil moves, the miiror picks up the beam of light and flashes it up and down on a strip of light-sensitive paper. If the sensitive paper is moved at a given speed a wavy line appears, with the height of the waves directly proportional to the stress in the propeller. The permanent record thus obtained can be studied at leisure and gives the engineer an exact idea of what is happening in the blade. An advantage of the instrument is that it lends itself to remote control and is portable.

PALLADIUM PRINTS

PALLADIUM is being used in solution for hand-sensitizing photographic papers in order to print high-quality photographs of the sort formerly obtainable only by using platinum.

GLARE-FREE DESK LIGHT

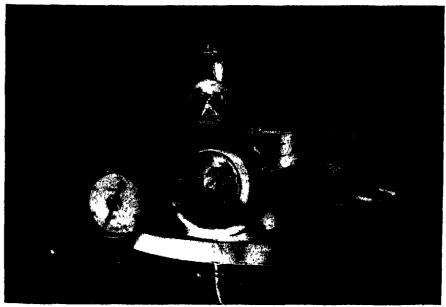

VISION without glare, bright illumination with no eye fatigue, greatly improved contrasts in viewing black and white illustrations, and truer, richer perception of colored objects, all this is accomplished by a new polarized-light lamp which can be used on desk or table. It is of moderate

Polarized light-no glare

height and has a circular metal shade with an internal reflecting surface. All light is thrown downward so that no direct light reaches the eye.

A new transparent plastic material polarizes the light as it is reflected downward by the metal shade. This new plastic polarizer, known as "Pola-Ply," was especially devised for this light by Alvin M. Marks of Polarized Products Corp. It is a composite plastic sheet containing no polarized crystals and which polarizes by virtue of the transmission of light through many layers of extremely

A glass-topped turn-table was devised by Goodrich engineers to make possible direct photography of the action of an automobile tire tread on a film of water. The turn-table is revolved while a camera placed beneath it takes photographs of tread action, showing in the laboratory the results of braking and other factors to which the automobile tire will be subjected as it rolls along the payement

thin isotropic plastic sheets. These sheets are sealed tightly during manufacture

This unique material can be produced in unlimited quantities for a small cost per square foot, and it promises to have many uses in the lighting industry.

SULFUR AIR POLLUTION

RECENT studies of the concentration of sulfur dioxide in the air in five important industrial areas of the United States show that this is a negligible factor in its physiological effect. As a result of some 50,000 separate analyses covering a period of 15 months, with samples taken within a 15 mile radius of the center of the area, the following figures were obtained St. Louis—East St. Louis—

Average 0 128 parts per million (maximum 2 266).

Pittsburgh—Average 0.037 parts per million (maximum 0.897)

Detroit -- Average 0.028 parts per million (maximum 0,396)

Philadelphia Camden

Average 0 027 parts per million (maximum 0 424).

Washington-

Average 0 009 parts per million (maximum 0 290)

Apparently Pittsburgh, in spite of its reputation, is not the leader in this type of air pollution D/H. K.

HEAT LAMP PROVES EFFECTIVE

POR the rehef of various deep-scated congestions, the 10-wait heat lamp recently made available by General Electric has proved particularly effective and convenient in use. The lamp utilizes a lamp constructed of infra-red transmitting black glass with a reflector, and has been designed to concentrate infra-red rays directly at the point of application. These penetrating rays augment

New, compact heat lamp in use for the local treatment of congestion

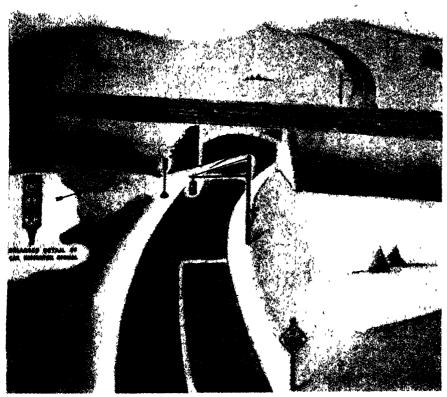

the normal blood processes, thereby relieving congestion

Simple and safe to operate, the lamp is of light-weight aluminum with an ivory baked-enamel finish. It has a handy switch and permanently connected all-rubber coid. The lamp draws 10 watts at 110 volts, and may be used with either alternating or direct current. Its compactness makes it convenient to carry for travelers who may desire relief from sinus afflictions at short notice.

STATE BIRTH CONTROL PROGRAM

NORTH CAROLINA is the first state in the nation to have a birth control program sponsored by the state health department.

Nearly half the counties of the state now have birth control clinics. There has been no local opposition to the service or the method

Highway safety may be increased by installations such as this one

adopted for rendering it. Social, religious, and other civic leaders have given their full endorsement and co-operation.

The patients have been selected from poor married women who need to limit the size of their families or space their children for the sake of their own and the children's health. Women who are able to pay a private physician are encouraged to do so. Practicing physicians in the communities served have been glad to find that they may legally give this service to their private patients.

A total of 1141 patients have been served, with only six failures reported. In three of these the mentality of the women was very low.—Science Service.

SPEED CONTROL SYSTEM

POR dangerous curves, highway hottlenecks, underpasses, and the like, the Automatic Signal Corporation has developed an ingenious speed control system called the Electromatic Our illustration shows an installation at an Scurve underpass.

In the foreground near the speed limit sign is a vehicle detector inset into the pavement. On the right near the railroad bridge is a traffic light, with one red and one green or orange light, controlled by the detector. To the left, nearer the bridge, is a car indicator signal which, despite its position at the left, is intended as a guide for the car in the right lane. Beyond the railroad is a duplicate set of detectors and signals to guide the oncoming left-lane traffic.

The traffic light is normally red. As a car passes over the near detector, it must slow down and wait a given number of seconds until a "proceed" indication, governed by local preferences, is flashed by the traffic light. The car then proceeds into the curve and under the underpass at a necessarily reduced rate of speed. After this car passes, the traffic light automatically returns to the red, or stop, light. Adjustment is made to

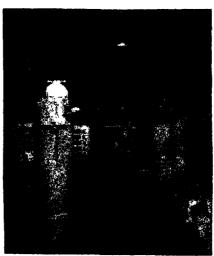

take care of a number of cars travelling in the same direction at rather close intervals.

When a car has gotten the "proceed" signal from the traffic light, the car indicator signal on the opposite side of the blind spot flashes on, spelling out "c-a-r," to warn approaching drivers

DIESEL CONTROL CABS

THE control cabs of the new streamlined 6000 horsepower, Seaboard, Diesel-electric locomotives, the most powerful and longest in the world, look very different from the cabs of steam locomotives, as our illustration shows. Safety in operation is an important factor, essential controls of the Seaboard Air Line Railway's Diesels consisting of a dead-man control pedal which would automatically stop the train if the engineer's foot should leave the pedal, a throttle lever controlling the speed, a reverse lever, and an air-brake lever.

The engineer is always given immediate

In a Diesel-electric locometive cab

information as to the condition of his operating equipment. An eight-inch electric gong and illuminated annunciator box is also placed both in the cab and in each engine room to inform the engineer of any abnorn al condition in the power plant or chassis. The annunciator boxes have three differently colored lenses which show if there is a hot engine, low oil pressure, or heating plant boiler failure. The alarm gong starts ringing the instant a warning light comes on and continues to ring until the engineer closes the throttle to stop the train. Windshield wipers, defrosters and visors, electric horns, safety glass, and speedometers all contribute to safety.

SWIMMING POOLS

GROWTH of algae in swimming pools is prevented by a grayish, white powder dissolved in the water. The treated water is not colored, does not stain suits, and is not objectionable to bathers.

DEATH RAY FOR INSECTS

COLD-BLOODED inhabitants of the fur of dogs and cats, of birds and their cages, lofts, and coops—fleas, ticks, lice, red mites—now have their own private death ray. A new infra-red lamp, developed by the Leray Corporation, kills all such vermin and others which infest seeds, cloth, wood, and

"Flea killer" in use

other materials. Fungus is also said to be susceptible to its killing rays, so that plants may be freed of disease fungi.

At present most of the emphasis on the killing power of this light is being placed on its use to rid household pets of vermin. Abercrombie and Fitch Company, New York sporting goods store, through whose courtesy we show the accompanying picture, advise that they are daily making very satisfactory demonstrations on dogs that are brought into the store. One treatment, naturally, is not sufficient to eradicate all vermin on an animal. The reason for this is not that all pests on the pet do not succumb at once but because the vermin often leave their "hosts" for short periods, especially after they have eaten well and are sleepy. The pet is therefore used as a lure or trap to facilitate cleaning of its quarters.

The Leray lamp is as easy to operate as a flashlight. It is held close to the animal's body, as shown in the photograph, while the operator's other hand ruffles the fur so that the light will penetrate to the skin. That is all there is to it except that often it is necessary to accustom the animal to its presence

Why Do So Many Presidents Enroll with the

ALEXANDER HAMILTON INSTITUTE?

MORE than 50,000 presidents and owners of American business concerns have enrolled with the Institute for executive training.

Why?

Because they know that organized knowledge of business is an essential

qualification to every responsible executive.

Because they know that modern business is too big to learn by personal experience alone.

Because they know that the Institute has gathered the experience of the most successful business men of America and the proved principles and methods of thousands of companies; formulated and organized this knowledge for their use.

Because they know that modern business has set new standards of executive competence and that the Institute training prepares them to meet these standards.

To Executives and Coming Executives The Institute Offers

ORGANIZED KNOWLEDGE of BUSINESS

The Institute training is not for Presidents alone—but it is planned only for executives and those who are determined to become executives. The Institute offers the knowledge and training without which no man is

qualified for executive responsibility.

For more than a quartercentury the Institute has been preparing men for business management, giving them the thorough, organized knowledge of production, marketing, finance, and accounting essential to

competent administration. Many of those enrolled have been ranking executives who recognized their need for better equipment; many others have been far-sighted men, twenty-five years of age and upward, preparing in advance for the opportunities they know will come.

If you belong in either of these two groups the Institute offers you the ideas, experience, methods, and judgment of the most successful business men of America, formulated and organized to give you a confident mastery of tested, modern business principles and practice.

If you are determined to command a higher place in American business life, to qualify fully for executive responsibility, to win for yourself financial independence, then you will want to read "Forging Ahead in Business" with its important message to men who want to go far in business. A new edition of this famous book is ready and we will gladly send you a copy free. Just mail the coupon.

Among the many American business leaders who have helped to build the Institute's Course and Service are:

C. M. Chester, Chairman, General Foods Corp; Thomas J. Watson, President. International Business Machines Corp.; Alfred P. Sloan, Jr., Chairman, General Motors Corp.; Benjamin Rush, President, Insurance Company of North America; Frederick W. Pickard, Vice-President, E. I. duPont de Nemonrs & Company, Inc.; Fowler Manning, President, Air-Conditioning Division American Radiator Corporation; Robert H. Montgomery, Lybrand, Ross Brothers & Montgomery; John G. Lonsdale, President, Mercantile-Commerce Bank & Trust Co.; Clifton Slusser, Vice-President, Goodyear Tire & Rubber Co.; Samuel W. Reyburn, Chairman, Board of Directors, Associated Dry Goods Corporation; and many more.

by flashing it on for several short periods Death to vermin at any particular spot comes in from a fraction of a second to four or five seconds.

SYNTHETIC GLYCEROL

CLYCEROL, produced as a by-product of the manufacture of soap from fats, has become so important in the manufacture of synthetic resins, particularly those used in paints and enamels, that its synthesis is being undertaken to amplify the supply. The process of synthesis consists in chlorinating propylene, a by-product of cracking of petroleum, and hydrolysing with alkali the trichloropropane thus formed. One of the large oil-refining companies has already installed equipment for this purpose and expects to be able to produce glycerol at a fraction of its present price.—I) H K

MAJOR INDUSTRY

OUT of every \$100 of sales of organic chemicals in 1937, \$130 was spent for research, for which chemical manufacturers spent during the year, according to conservative estimates, \$20,000,000.

SIXTY YEARS

THE accompanying graph, prepared recently by, and used through the courtesy of the General Electric Company, presents some interesting contrasts. It shows clearly, by verifiable figures, that we are not yet quite licked b, the machine of man's own making. In fact, at the very point where the machine should have done the greatest part of its dastardly work, the evidence indicates that man is still the boss.

In approximately 60 years, the population of the United States increased 2.6 times. Had our machines of 1878 been left alone and had all other themes been equal, jobs in factories should have increased a like number

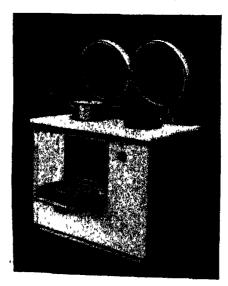

of times, or 2.6 times. But jobs actually increased 3 times. That means more jobs per capita, with the machine than without. Study of the graph will indicate other illuminating improvements in standard of living, money to buy the things for the better life, and so on

FLUORIDES IN WATER PREVENTS TOOTH DECAY

PRINKING water containing fluoride, a worry to residents of certain localities because it causes a permanent discoloration of the teeth of children, known as mottled teeth, may actually be a blessing in disguise.

Children drinking this water are relatively immune to tooth decay, it is revealed by a four-year study described in *Public Health Reports* by Dr. H. Trendley Dean, dental surgeon of the United States Public Health Service

Examination of thousands of school children in South Dakota, Colorado, and Wisconsin showed that the severity of dental caries is lower in localities where the mottled enamel occurs. In fact, the severity of tooth

decay is inversely proportional to the prevalence of mottled enamel.

A special study of nine-year-old children showed that the number of children completely free from tooth decay is over five times as high where the drinking water contains appreciable amounts of fluorides as where the water is relatively free from the mottling substance.

Dentists are not ready to advise drinking of the fluoride water to prevent tooth decay, but the research raises some interesting questions, Dr. Dean points out. "What rôle, if any, does the physical structure of a tooth play in either susceptibility to or immunity from dental caries?" he asks on the basis of these findings. Is the higher fluoride content of the enamel of a mottled-enamel tooth the immunity-producing factor? Is the limited immunity due, directly or indirectly, to the well-known inhibitory action of fluorine on enzymatic processes?"

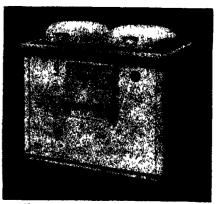

Perhaps it is not the fluoride that causes the immunity, after all, Dr. Dean points out, but some unknown constituent in water that either appears only where fluoride is present, or is in greater concentrations in water containing fluoride, or that acts to produce immunity only when associated with fluoride.

—Science Service.

FOR THE KITCHEN

SOME years ago we pointed out that invention per capita was higher in Switzerland than in this country. It seems that the Swiss are as ingenious as they are prolific inventor—if we are to judge by two new patented inventions recently described to us by Mr J. Basler, who is in this country to interest American manufacturers in their production.

Electrical ranges have the disadvantage that, when starting to cook, the housewife must wait until hot plates and oven are up to temperature. The result is that cooking is very slowly done. This delay is unnecessary with the Swiss range illustrated on this page It operates like an electric refrigerator—the current is on all the time. The body, the

Above and left: Two views of the electric kitchen range in which current is left on all the time

oven door, and covers over the hot plates are well insulated so that the exterior is comfortable to the touch. However, the housewife has only to lift one of the covers to find the hot plate heated to 270 degrees, Centigrade. Speedy cooking results.

Inside this unit is a strong, sealed tank of water which acts as an accumulator of heat. A heating element which consumes 600

watts and is turned on 24 hours of the day keeps a constant head of steam under pressure circulating under the hot plates and in the oven. An automatic regulator keeps the heat constant, turning the current on and off, as needed, exactly as does the control mechanism of an electric refrigerator. Inside the

The bottom is thicker than the sides in this latest one-piece saucepan

body of the range is also a coil connected with the water system to supply running hot water at all times.

Besides faster cooking, the advantages of this range lie in lower rates for current; the use of off-peak-load, or night current; prevention of burned food because of the even, controlled heat; and other features.

The other invention consists of a stainless saucepan, the bottom of which is of heavier "plate" than the side walls, but cast as one unit Besides the well-known advantages of stainless ware, this pan will not buckle or warp. It is particularly useful on all perfectly flat hot plates of electric ranges.

FOREST FIRES

A FOREST fire every three minutes was last year's count in the United States, according to summaties compiled by the Forest Service, U. S. Department of Agriculture. The total for the year was 185,000.

CASTOR OIL OFF THE MEDICINE SHELF

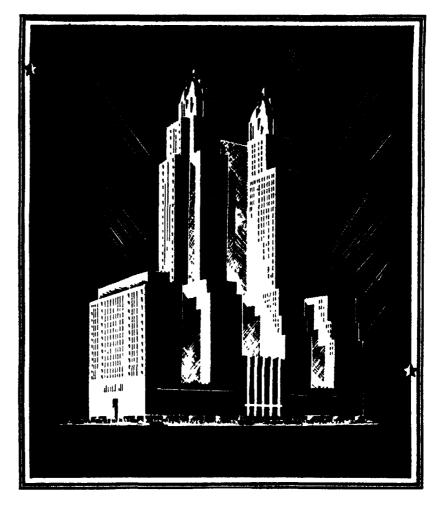

YOUNG America's acquaintance with castor oil does not include knowledge of the important fact that it is the only known lubricant which does not affect rubber. That makes it invaluable in hydraulic brake fluids widely used in modern automobiles. Brake fluids consist, with a few exceptions, of castor oil mixed with a solvent, such as alcohol, to make it thinner and to prevent it from thickening in cold weather.—D, H, K

BRITISH PRAISE NEW AMERICAN CRUISERS

IN the new crussers of the Brooklyn class, the U. S. Navy possesses the best ships of their type in the world. Such is the general tenor of an article in a recent issue of The United Services Review, leading British military periodical.

In armament, protection, speed, seaworthiness, plane-carrying capacity, the new American craft are given a long lead over the Mogami class in the Japanese Navy, and even admitted to have the edge over the comparable British cruisers, the Southampton class

The main armament of the Brooklyn class,

THERE IS ONLY ONE "WALDORF"

Its towers, sharply etched against the sky, are modern as tomorrow . . . yet its tradition of hospitality goes back to a grand and spacious age.

Its glamorous restaurants, favorite gathering-places of metropolitan society, are vibrant with music and gaiety . . . while above, its rooms are star-quiet in the night, peaceful as the hills of home.

Its guests include the great ones of a busy world... and the quiet, unassuming people who make that world go 'round.

15 6-inch guns, is the same as that of the Mogamus, but the latter ships have a displacement of only 8500 tons as against the Americans' 10,000, and are therefore rated as over-gunned by the British journal. They have purchased their heavy battery probably at the cost of other desirable qualities, such as armor and internal protection against damage by torpedo and mine explosions.

The Brooklyns carry four planes, and can accommodate as many as eight. This capacity, the Review comments, is far superior to that of any foreign cruiser save one in the Swedish Navy, which is a hybrid ship that has sacrificed everything to carry from six to eleven planes.

The British observers are favorably impressed with the anti-aircraft armament of eight 5-inch guns carried by the American cruisers, which is "very similar to that carried in the Mogamis and is slightly superior, at least in theory, to that in the Southamptons."

Unlike the comparable British and Japanese cruisers, the Brooklyn class carries no torpedo tubes. These weapons have been given up in all American ships larger than destroyers. The feeling of the Review seems to be that this is no particular disadvantage, since the new cruisers are designed to act in conjunction with the destroyer flotillas, and American destroyers now building carry the exceptionally heavy torpedo armament of 16 tubes.—Science Service.

PEACE

RINGING in the first one hundred years of peace between the United States and Canada, a large nickel bell known as the International Peace Bell has been installed on the lower ramparts of Fort Wellington overlooking the St. Lawrence River at Prescott, Ontario, where the "Battle of the Windmill" was fought in 1838. Over 15 inches high and weighing more than 200 pounds, the bell is made of a special nickel alloy.

STOP-WATCH-MAN

IN presenting an honorable mention award in the Scientific Group of its Third Annual Modern Plastics Competition to the Precision Scientific Company of Chicago for its Stop-Watch-Man, Modern Plastics Magazine recognizes the design achievement made possible with plastic materials.

The Stop-Watch-Man is a tear-drop shaped holder or base for a stop watch, for use in the laboratory where workers' hands are very

Stop-watch holder, made of melded plastic, for use in the laboratory

GLARE-FREE LIGHT POLA-LITE

Indirect illumination combined with a polarizing medium to produce the perfect lightforreading, studying, working

Throws wide radial field of light Light bulb is housed within an opaque shade, from which light is reflected downward through a sheet of a new composite plastic (POLA-PLY) that strongly polarizes light rays This polarized light, reflected from a printed page, illustration, or other surface, has no trace of glare, does not tire the eyes, even though you work under it for long periods of time

Polarized light from POLA+LITE is diffused, easy on the eyes. Gives greater contrasts in reading black and white type or illustrations. Truer, richer perception of colored objects is possible with POLA*LITE than with ordinary illumination.

Finished in beautiful brown lacquer and chromium trimmed

busy and often wet with oils or chemicals. A regular stop-watch is recessed into a Bakelite molded plastic base, so constructed as to permit control mechanism to be set into the base and the watch operated by merely pressing a button. Designers Barnes & Reinecke of Chicago achieved not only a better-looking, better-functioning unit utilizing plastics, but also were able to reduce manufacturing and, consequently, selling costs, compared with an older cast metal model. The Chicago Molded Products Corp., Chicago, did the molding job, using Bakelite.

GRINDER BECOMES VERSATILE

JOBBYISTS and lovers of fine tools who are fortunate enough to own a DeLuxe Handee, made by Chicago Wheel and Manufacturing Company and described in these pages some months ago, may now purchase a number of accessories to make it into a

Hand grinder in a drill press

far more versatile tool. An accompanying photograph shows a simple mounting which turns it into a drill press. Other simple attachments, or rather, holders, convert it into a router and shaper. The Handee Workshop is a kit which makes possible its use as anyone of 12 machines; lathe drill press, router, grinder, polisher, sander, saw, shaper, and so on

SONIC SOFT CURD MILK

THE Submarine Signal Company has specialized for years in the development of electro-mechanical vibrational apparatus of all sorts. One interesting product of this work has been the development of a method and equipment for introducing soft curd characteristics into milk by the application of sonic energy. Sonic energy-high frequency vibrations and its effect on the

DON'T let your friends poke fun at your "bay window"! If the Vito Belt does not make that paunchy belt line appear slimmer... it won't cost you a red cent! Whether "Nobody loves a fat man" is true or not, it is certain that no-one admires his appearance. If you want to have that well-set-up look, just get into a Vito Belt!

Safe Girth Control!

No man wants to appear ridiculous, yet health is more important than looks. Take care of that ugly paunch the safe way... with a Vito Belt. Excessive exercise may strain your heart, especially if you are over 40...dieting and drugs may be dangerous. The Vito Belt not only gives you that military carriage and improves your appearance, but also brings welcome support to strained abdominal muscles and sagging internal organs.

Support With Comfort!

The Vito Belt is made in several styles. The one illustrated is of pure Para rubber, molded to give maximum support. Hundreds of tiny perforations allow air to penetrate to the skin surface, keeping it cool and halping to evaporate the body moisture. The special lace back permits you to adjust the belt to take care of any change in your size and at the same time give you the needed support.

SAGGING ABDOMINAL WALLS MAY CAUSE TROUBLE

Waistline fat often stretches and weakens abdominal muscles, allowing stomach and intestines to fall forward and downward. When these muscles are comfortably supported with a Vito Belt you will feel more like going places and doing things.

MAKE A 10 DAY TEST . . . et our expense i You'll never know what amazing results are possible until you wear the Vico Belt. You owe it to yourself to take advantage of our 10-day TRIAL offer. Don't Wait MAIL

> •••••••• HAMILTON BELT CO., INC. 171 Hill Street, New Haven, Conn. Gentlemen: Send me FREE illustrated folder describing the Vito Belt and giving full details of your Trial offer.

subject of considerable research by Dr. Leslie W Chambers.

Ordinary cow's milk is assimilated with difficulty by many adults as well as children, due to the large, tough curds formed in the stomach by the initial reaction between the ingested milk and the stomach juices. The necessity for some effective and inexpensive treatment by which the curd formation can be altered to a more easily digested form is shown by the universal practice of modifying cow's milk by various expedients, before feeding it to infants, so as to give a more readily digested curd.

The apparatus used to apply the present process to milk consists of a stainless-steel

Two-foot stainless-steel diaphragm set-up for the sonic treatment of milk

diaphragin approximately two feet in diameter which is vibrated electromagnetically at a frequency of 360 vibrations per second. A stainless-steel cover is provided, as shown in the photograph, which can be bolted against the diaphragm, thus forming a chamber. The milk to be treated is introduced into this chamber through the inlet opening at the outer edge of the cover and in order to pass out of this chamber must of necessity flow over the center of the diaphragm where it is subjected to intense vibration before passing out through the centrally located outlet opening in the cover. The unit shown is capable of handling milk at the rate of 250 gallons per hour with a power consumption of approximately five horsepower.

Curd formation in the stomach as a result of this process is uniformly small and readily digested. During the process the cream in the milk is distributed through it so that no cream line forms on the top of the bottle. It is interesting to note in this connection, however, that although the butter fat particles are distributed through the milk by the process the particles are nevertheless large enough so that subsequent recovery of the cream from returned milk is readily possible by passing it through the ordinary type of separator.

Feeding tests on children and invalids who previously had difficulty in assimilating ordinary milk have demonstrated that the process definitely increases the digestibility of the milk without addition to or subtraction from the ordinary constituents of normal whole milk.

RUBBER TROLLEY GUARD -Safety for Mines

THE exposed trolley wire has long been La danger to workmen in those mines where electric transportation is used in the main entries. Even when the greatest care is taken to prevent body contact with the wire, there is always the possibility of serious injury or death occurring to a miner due to

SCIENTIFIC AMERICAN 24 W. 40th St., New York City, N.Y. his touching it with the tools which he is

Trolley wire guards of wood or old fire hose have been used, but both offer disadvantages. Too often the wood guards are made from old or inferior grades of lumber and are easily broken. Use of old fire hose as a wire guard offers an advantage in that it is flexible. However, it does not offer perfect protection due to the fact that the yarn in such hose acts as a conductor of electricity.

A solution to this problem is offered by The B. F. Goodrich Company, in the development of a new rubber trolley wire guard de-

No more shocks from mine wires

signed especially for mine service. This guard is made of cloth-inserted sheet rubber, 3 32 of an inch thick by 9 inches wide, which 18 folded double and cured in a permanent "U" shape It provides complete protection for the workmen because the material flexes or bends in either direction. Installation is simple and economical. All that is necessary is to notch the rubber guard to fit around the trolley wire support and place it over the wire like a saddle.

Man Still Champion of the Air

DIGRESSING for the moment from the usual types of scientific investigations which ordinarily occupy his time, an industrial research scientist has exploded-with proofs aplenty in different ways-a fantastic yarn about an insect that flies so fast that it arrives before you hear it leave-a fly with a speed of 818 miles an hour (sound travels only 740 miles an hour).

The scientist is Dr. Irving Langmuir, associate director of General Electric's research laboratory and Nobel prize winner, the fly whose reputation he has smashed is the deer bot fly, which repeatedly in recent years -and more and more as time has progressed—has been held up as something which has far outstripped man's puny efforts to become flight-speed champion of the living world. Man's fastest planes hurl themselves through the heavens at a mere rate of hardly more than 400 miles per hour.

Particularly in recent months have there been cartoons and news items referring to the speedy deer bot-fly or again simply to the

Now Dr. Langmuir has shown:

1. The non-streamlined-and really flatheaded—fly at such a speed would encoun ter a wind pressure against his head of about eight pounds per square inch, probably enough to crush him. R=pd2v2f is his proof.

2. Power consumption for maintaining a

changeable in easy-working chuck to grind, drill, pollsh, engrave, sharpen, carve, sand, saw, rout, cut, etc. Set up shop anywhere; plug in AC or DC socket.

velocity of 818 miles per hour would be about one half horsepower which, for a fly, would be a good deal.

3. If the fly equals man in efficiency—and it doesn't seem as though the fly can be more efficient than man who as an organism himself has a high thermodynamic efficiency—the fly must consume 1.5 times his own weight of food each second to deliver the 370 watts, or nearly half horsepower of energy, which such speed requires.

4. A piece of solder of roughly the dimensions of the fly can be seen only as a blur if, in a brightly-lighted, white-ceilinged room it is attached to a silk thread and awung so that its speed is 13 miles per hour; at 26 miles per hour it is barely visible; at 43 miles per hour it appears only as a faint line and its direction of flight cannot be told; and at 64 miles per hour the solder "fly" is invisible. (The higher speed attributed to the fly was based on a published report of an entomologist that he had seen the insects fly past him so fast that they could be seen as a blur, and that he estimated their speed as 400 yards a second, or 818 miles per hour.)

5 Laboratory light intensity measurements and calculations also prove that an object the size of the deer fly is invisible at speeds of 64 miles per hour and above.

6. A fly striking a person at such a speed would exert a force of 310 pounds, or about four tons per square inch, and would penetrate deeply into human flesh—and the first such instance is yet to be reported, and finally,

7. Dr Langmur concludes a speed of 25 miles per hour is a reasonable one for the deer fly, while 800 miles per hour is utterly impossible.

Aviators, then, do not have to hang their heads in shame because they can hardly surpass 400 miles per hour with today's airplanes. Nor will they ever have to move over in their courses to give the right-of-way to deer-fly speedsters.

LARGEST

THE largest steam locomotives in the world are in operation in the United States. The boiler barrel of one of these locomotives, if all tubes and other obstructions were removed, is large enough to permit any standard automobile to be driven through with room to spare.

LIGHT BEAM USED IN COLOR MIXING

THE principle of interrupting a beam of light to make precision measurements has been put to a new use, according to J. W. Strain, of the Acme White Lead and Color Works.

Taking a leaf from the experience of other branches of industry and science which have been utilizing light-beam measurements for a number of years, the Acme Color Eye measures the exact level of color poured into a container by interrupting the light beam when the color has reached the desired level. The operation of the device is very simple: required proportions of basic tinting colors are indicated on the large lighted dial. This automatically establishes the level of a trans-

"Amateur Telescope Making -Advanced"

NOT a new edition of "Amateur Telescope Making," but a brand new and entirely separate, companion volume, though printed and bound uniformly with it. This new book has 57 chapters, 650 pages, 359 illustrations and over 300,000 words. It is not recommended to beginners, as it follows logically after the first book, "Amateur Telescope Making." The following is an informal, running description of "Amateur Telescope Making—Advanced ('A.T.M.A.')."

The book is in two parts. Part I, with 45 chapters, is on practical construction. Part II, with 12 chapters, is on some of the more practical aspects of observing.

PART I

Everest's advanced mirror technic, Selby's flat technic; eyepiece making; objective lenses and refractor mountings in greater detail than in "A.T.M"; drives; Schmidt camera; aluminizing; the new Zernike test; setting circles; indoor telescope; sidereal clocks; observatories, detecting astigmatism; making micrometers, chronographs; metal mirrors. Many other items.

PART II

Systematized observations; meteor, stellar and eclipse photography; the eye and the atmosphere in observation; reflectors versus refractors; "richest-field" telescopes, and a wealth of other material.

Light beam makes possible automatic measurement of paint colors

parent rod which extends into the mixing can. A light beam travels down this rod of special transparent composition and is reflected in the surface of the color in the can. The instant the color reaches the correct level and touches the end of the illuminated rod, the reflection automatically disappears, giving an instantaneous stop-pour signal.

Experience has proven that this type of signal is so quickly telegraphed to the hand that pouring stops instantly

New Wood Preserva-

TIVE

PENTACHLOROPHENOL, now produced on a comment duced on a commercial scale, has been found to be a particularly effective material for the treatment of wood for preserving it against decay, termites, and other destructive forces. It may be applied as a 5 percent solution in a petroleum solvent, preferably by pressure impregnation or by brush treatment. The advantage of the new chemical as compared with creosote and other familiar materials is that it does not change the texture or painting properties of the wood and possesses practically no odor. It can be used for treating heavy timbers or for the preservation of finished mill work. Although it is difficultly soluble in water, it forms a compound of sodium which is readily soluble and can be used for controlling slime and algae in industrial water supplies and as a preservative for glue and other similar materials subject to decomposition by bacteria or fungi.-D. H. K.

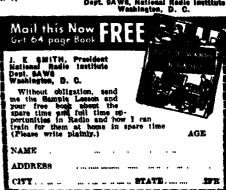

DEW PONDS AGAIN

PREHISTORIC Britons, confined to waterless hillsides by wolves on the plains, obtained water for their cattle by constructing mysterious dew ponds. Slightly below the crest of a hill, a shallow pit was dug and lined with straw; a layer of puddled clay was added, and gradually a pond appeared, filled with water from an invisible source. Day after day the berds drank, yet

the ponds remained filled, fed by moisture condensed from the air.

Modern scientists are not yet certain why dew ponds work so well, nor do engineers know the conditions necessary for duplication elsewhere. Natives say that the only known successful builders today are from a single English family who use inherited methods, except that concrete replaces clay. The bed of chalk running from the Weald of Kent through the Sussex Downs to Wiltshire is the only subsoil known to support these ponds. Whether the chalk is essential no one knows. George and A. J. Hubbard. British scientists, once wrote an able and fascinating treatise on the subject, but they were unable to duplicate the results.

Obviously a dew pond must condense more water than it evaporates, which means that it must keep cool. It must lose heat otherwise than by evaporation, and must not absorb heat unnecessarily from the earth Recent research has shown that water is nearly perfect as a "black body" or a body that easily gives off heat by radiation. and this discovery may furnish one key to the dew pond's efficiency. The balance is delicate and the straw which keeps away the heat of the earth must be kept dry. The flint men protected their straw insulation carefully against moisture, and 20th Century man suffers by comparison when be finds ice between clapboard and plaster in his insulated home. To the men of the hill, such ignorance of nature's ways meant victory for the wolf pack.

Nearly 3000 years have passed since the Neolithic hill-man fought off wolves with organized trench warfare, defending his herds and his temples of the sun "Trolls, kelpies . . . pixies, gnomes and the rest-gone, all gone!" But dew ponds remain to intrigue and mystify the sages of a modern day - The Industrial Bulletin of Arthur D. Little, Inc.

THE CHINESE ARE NOT RACIALLY ALIKE

R. Chungsee H Liu has attempted a VI classification of the races of China in which he points out that the Chinese people are by no means a homogeneous unit, as commonly supposed, and examines critically the classifications of those anthropologists who have recognized this fact. Mongol, Mongo loid, and Mongolian, are loose and unsatisfactory terms, and Homo sinicus is suggested to replace them

In the Chinese population as a whole, the physical characters are, in general terms: hair miversally black, lank or coarse. straight, with almost circular cross-section. body and face hair very scanty, skin varying from yellowish to yellow-brown; eye color light-brown; setting of eyes horizontal or oblique with epicanthic fold; cheek bones prominent; medium to broad-headed; nose relatively flat with depressed nasal bones; medium stature; slender or thick-set; hands and feet small.

Jan 30

Hadden,

Within this general description, three types are recognized, which are distributed in accordance with the three great river-systems of China: (1) The Huangho type in the north, mainly found in the valleys of the Huangho, the Liao Ho, and the Sungari Rivers in Manchuria. This type is of high stature, long-headed, slender-nosed, and of Established 1853

vigorous physique and robust feature. It is honest and frugal, slow but sure, chivalrous and conservative. The people speak the northern Chinese mandarin, and may be regarded as the archaic type of Chinese. (2) The Changkiang type, mostly confined to the Chang Kiang or Yangtze River valley in a favorable natural environment. This type is of medium stature, of medium head width and medium nose height, with light yellowish complexion. The people exhibit great iterary power and ability. They speak southern Chinese mandarın with local dialects—the progressive type of the Chinese nation. (3) The Chukiang type in the Chu Kiang or Pearl River valley of southern China, with Fukien as an eastern corridor and Hainan Island beyond the sea They are of shorter stature, broad-headed, low-nosed, of darker skin color. Mentally this type is vivacious, and adventurous, quick in action and radical in thought. They speak various dialects of southern China -Adapted from Nature (London)

NEW INSECTICIDES

BRITISH research on chemicals for the control of pests has recently revealed the fact that several unusual compounds ordinarily used for other purposes possess merit for controlling insects Tetramethylthiuram sulfide, a valuable accelerator in rubber vulcanization, repels the Japanese beetle. Methyl bromide has been found to be even more toxic than hydrocyanic acid for several types of moths and larvae and is being used effectively against granary weevils. Phenol thiszine is being studied as a substitute for lead arsenate. Dichloroethyl ether, used as a solvent in refining petroleum, has been found effective in killing the wire worm.—D. H. K

Homing Pigeons EXPOSED TO RADIO FREQUENCY WAVES

CCASIONAL reports have appeared from time to time to the effect that radio waves disturb the homing instinct of homing pigeons. One of these reports covers tests conducted by the Navy Department at Lakehuist, New Jersey, and shows quite conclusively that the pigeons were affected. Those exposed to radio waves at the antenna of the A. T. & T transmitter at Ocean Gate, New Jersey, took much longer to return

SOILLESS **Growth of Plants**

by Carleton Ellis and Miller W. Swancy

THE flist complete treatise in book form on this immensely important subject which discusses thoroughly all three methods of Soilless Growth-Water Culture, Sand Culture and Sub-irrigation

Interesting timely and instructive both to scientists and laymen is this new comprehensive book on the art of growing plants without soil Probably no technical development of the past decade has made a more triumphant entrance into the realm of lay science than has the soilless growth of plants So important is this new development in plant growth, that the National Resources Committee selected it as one of the few recent technical advancements likely to help fushion the future of this country. So fascinating is this method of growing flowers vegetables and fruits, that the desire to try out this 'new way is spreading with phenomenal speed.

home than did those birds released at the same location but not exposed.

In order to find out, if possible, what were the effects of radio waves on pigeons, a 190watt oscillator was constructed in the laboratories of the Zenith Radio Corporation under the supervision of Commander E. F. McDonald, Jr., the organization's president, and a series of experiments were conducted at many different wavelengths on homing pigeons. The oscillator was arranged to have large tank coils so that the pigeons could be placed in a strong field. The oscillator was adjustable over a range of five to 50 meters.

The pigeons were released one at a time at suitable intervals. The tests were carefully arranged so that only certain pigeons were exposed to radio frequencies. The remainder were kept 1/2 mile away from the oscillator, mside a steel bodied truck.

Tests were conducted under these conditions at Mount Prospect, Illinois, beginning October 13 and continuing through October 27, with the following results.

Average Time

2614 Minutes

Flight course 25.6 Miles About 125 pigeons flown during entire tests Above compilation covers 40 pigeons

It appears from these figures that homing pigeons exposed to radio frequencies are affected by the exposure and that in some way their ability to return home does slow up The difference in time used to return home between the exposed and the unexposed birds is not very great; however, it must be borne in mind that the power of the oscillator is not great. Considering this, the results obtained become significant.

During the course of these experiments many other tests were conducted. In some cases fixed permanent magnets were hung around the necks of pigeons. This was done to determine whether or not the pigeon's homing instinct might not result from some ability on its part to be guided by the earth's magnetic lines of force or, as has been suggested, since there exist no two places on the earth's surface having the same magnetic field strength, these birds might seek that field strength which exists at the home lofts. It was found that the magnet on the pigeon's neck did not seem to affect his homing ability at all. Further tests of this type might produce more conclusive evidence. However, the present tests indicate that the flying time is the same both with and without the magnet.

It has been reported that homing pigeons having their ears blocked up fail to return to the home loft. The use of wax in the ears seems greatly to irritate the pigeon. In order to make this test under conditions where the pigeon would not be irritated in any

New York

way and would be normal in every respect, except that his hearing would be stopped, the ears were completely filled with Vaseline. The feathers all around and over the cars were also smeared with Vaseline. The temperature on the day of the tests was around 45 degrees and the Vaseline quite solid at this temperature. The pigeon so treated returned home faster than it had ever been known to do so before, and with the Vaseline still in its ears. It is possible that further tests might develop additional information; the fact that the pigeon returned home in very much faster time is at variance with other reports which indicate that the pigeon loses his homing instruct entirely when his ability to hear is removed.

Several tests were also conducted where an antenna was coupled to the oscillator and a half-wave antenna, of very small wire, tuned to the transmitter frequency, was tied to the pigeon's leg so that there was actual contact to the leg. This seemed to slow the bird's flight up somewhat and it is difficult to say whether the slowing up was due to the drag of the antenna or the resultant application of more radio frequency to the pigeon through the medium of the antenna

This test would be of real merit in the vicinity of a regular transmitter having considerable power.

The facts produced from the experiments would indicate that the pigeon's organs of hearing apparently are not connected with the homing instinct is not affected by magnetic fields such as the earth's field, that radio radiations do affect the homing instinct, and that the homing instinct is not appreciably affected by any particular wavelength in the short wavelength ranges, any wavelength producing about the same results.

It is of interest to note that exposure to radio frequencies in the ranges tested, often seemed to make the pigeon restless and that at 20 meters the respiration and heartbeat seemed to increase a noticeable degree and to an extent much more noticeable than at any other wavelength in the range used.—C. E. Brown, Zenith Radio Corporation

RADIUM HOUNDS

(Continued from page 8)

suspected thief, as well as all likely caches, could be searched entirely without his knowledge. Even his home could be thoroughly "ransacked" by the unobtrusive method of parking a car carrying a Geiger-Müller counter in front of it.

With the increasing use of radium in medicine, the manufacture of "radium hounds" is on the rise. About 20 of these devices are now being used in the United States. Some of them are home-made affairs. but at least two companies manufacture them for the trade, at an approximate cost of \$125. Are the machines effective? Of the 107 radium losses mentioned above, 59 complete recoveries and 11 partial recoveries were made by "radium hounds." The radium thus recovered represents several hundred thousand dollars in cash, also the removal of a grave potential hazard to any human being who might unconsciously come in contact with this burning element. Since the advent of the "radium hound," I know of no instance in which anyone has been serienaly injured by lost or misplaced radium.

PICTURE-MAKING BY Enlargement

TIME was when the contact print was L taken for granted and only the so-called "advanced" amateur and professional went in for enlarging his pictures. But with the advent of the miniature negative, the enlarging camera became essential equipment A great many amateurs today use an enlarger as a matter of course not only because the miniature negatives most of them make cannot be seen properly in a contact print

Courtesy Federal Stamping & Eng Corp Focusing the enlarger

but chiefly because of the many opportunities afforded by the enlarging medium for improving the final result

Undoubtedly the chief attraction of the cularging medium in photography is the large print The mere comparison of a small contact print with a 5 by 7 or 8 by 10 enlargement of the same negative image is enough to sell the enlarging idea to practically any photographic worker. But more wonderful even than this is the remarkable fact that by the same token and in the same way that the negative is enlarged to greater proportions, a mere portion of the negative may be selected and magnified to occupy the full format of a good-size print. The opportunities thus afforded for recomposing the arrangement of the negative image, for altering the emphasis of certain details, for introducing a special meaning that may not have been perceived in the original subject as recorded on the negative, are all too obvious to require more than mention. Moreover, it is no mean advantage thus to be able to delete extraneous matter, particular-

ly when the focal length of the lens or an enforced vantage point made it necessary to include more than was actually wanted

Control in printing, more familiarly known as "dodging," is practised most effectively during enlargement. Suppose, for example, you project on the easel a negative image in which the shadow detail is abnormally lower in the tonal scale than the detail in the brightest highlights, For the best possible enlargement from this neg ative, you will want to show detail in both highlights and shadows. If you were to expose for the highlights you would lose or badly damage your shadow detail, and if you exposed for the latter, your highlights would very likely show little more than white paper. In order to get both shadow and highlight detail in an enlargement from the negative mentioned, you will have to resort to the procedure known as dodging This is done by attaching a piece of cardboard or wad of cotton to the end of a wire which is held in suspension for the required time between lens and easel. The dodger is cut or shaped to the required size and form and agitated during the exposure In this manner, relatively transparent or thin areas are held back, relatively dark or dense areas are permitted a longer print ing time by the use of a cardboard large enough to more than cover the size of the paper on which the print is being made and with a hole cut in it so positioned and of such a size as to permit the dense area to pass through while the rest of the negative is completely shaded

Another interesting printing method is that of the photomontage made by projecting a number of different negative images

Dodging

For photomontage work

on the same sheet of paper As each image is projected in its allotted space on the paper, the rest of the paper is shaded, as shown in the illustration or by some similar method. Before actual operations are begin, a plan must, of course, be laid, and the individual negatives projected and spaced off on a plain sheet of paper which, thereafter, becomes the guide for the projected images. Adjoining areas are made to merge into one another and should not show sharp, delimiting lines.

Distortion of the negative image is accomplished during projection by tilting the paper easel in relation to the enlarging camera lens so that the image is either elongated or broadened, depending on the position of the easel with relation to the projected image. Tilted buildings caused by an upward tilt of the camera in making the exposure may be corrected under the enlarging lens by a contrary tilt of the easel, thus bringing the building upright again.

These are the principal uses of the enlarging process and many workers see in them more than their money's worth in the purchase of an enlarging camera

World's Fair Pictures

THE ability to "see" pictures is rarely so well demonstrated as in the work of Richard Wurts, of New York City, a widely known photographer, who recently exhibited more than 50 pictures of the New York World's Fair in the making. Held at the Museum of the City of New York, the display marked Mr. Wurts' first one-man show and well deserved the wide attention it received. Those photographically minded were impressed with the implied proof so graphically displayed that picture materials may be found in relatively unpromising surroundings provided the photographer has "what it takes" to pick them out.

When asked why he had taken the trouble to make pictures of subject-matter that was merely preliminary to the real and completed thing, Mr. Wurts explained that primarily what he was interested in was not so much the identity of the subject-matter itself as the opportunity it afforded for obtaining striking pictorial effects. Incidental to this but none the less worthy of the efforts he had expended in shooting the pictures was the documentary or historical aspect

Scientific American

of the pictures which, once the Fair construction was completed, could never be made again. One of Mr. Wurts' World's Fair photographs appears on the front cover of this issue and another on page 24

NEW SCHEINER RATINGS

THE announcement that Kodak Super XX, introduced in the 35-mm size, is now available in all the popular roll-film sizes and in film packs, is accompanied by Scheiner or Photoscop ratings for the new Eastman films. These ratings, which supplement those for the Weston and General Flectric systems announced in a recent issue of this department, are as follows

	Daylight	Mazda light
Panatomic X	25	23
Plus X	26	24
Super XX	29	27

These ratings are intended for average exposures and are not intended to be the maximum speeds. Negatives made with half the exposures called for will be quite satisfactory under ordinary conditions, but where the subject includes much shadow detail, for example, it is not always wise to attempt the shorter exposures. As a general, practical guide, the speeds indicated will result in fully exposed negatives.

Y.M.C.A. CAMERA CONTESI

YOUTH holds the limelight in an international photographic contest under the auspices of the National Council of the Young Men's Christian Association of the United States. The contest, which closes February 15, 1939, is open to amateur photographers throughout the world. Winning photographs will be used in the decorative scheme of the Young Men's Christian Association Building now being erected on the World's Fair Grounds in New York City

Submitted photographs must picture the life and activities of present-day youth in the five following classifications; Youth at home; Youth at work, Youth at play; Youth and citizenship, and Youth at worship. There is a first prize of \$25 and a second prize of \$15 in each group, with an additional grand prize of \$50 for the best photograph in the entire contest.

Contest rules limit entries to work of amateurs, require that pictures must fit one of the given classifications, and that prints must not be smaller than 8 by 10 inches, black and white. All entries must be in the hands of the Photograph Contest

WILLO JR. ENLARGING EASEL

The Willo Jr, Enlarging Easel holds paper up to 11 x 14 inches and has a built-in adjustable margin device that is operated by a gentle push or pull. This lever accurately adjusts the upper and left margins to any size between 1/16 and 2 inches, as indicated on the conveniently located scale. There are no loose parts to be lost and no possibility of unequal margins. The sturdy metal masking bands keep the paper flat on the board and prevent curling.

Locks automatically Simple to operate Nothing to get out of order, Will last for years

NEW RECORD PAPER-STRIP PRINTS

And What They Mean To Your 35 mm. Negative Film Roll

Tainger-prints and scratches on the negative film give very undesirable results and may spoil your otherwise perfect picture, especially when enlarged. These marks are usually caused by the constant handling of the negative which can be entirely avoided by using RECORD STRIP PRINTS. • These Strip Prints are made on a special printer with a Photoelectric Exposure Control which grades each frame individually and reproduces the true quality of your negative so that you know what you may expect of your enlargements. quality of your negative so that y
you may expect of your enlarge

All exposures (except those which are blank or entirely useless) are delivered to you on ONE Strip. Also showing on each frame the negative number. Using these quality Strip Prints, there is no need of handling the negative film roll. Your Negative Film Roll and the RECORD STRIP-PRINT are delivered to your in one doublesseled container. you in one double-sided container you in one gouble-sided container . Sefe-guard your negative by insisting on RECORD STRIP PRINTS made in this scientific man-ner, at your dealer or write to us direct and we will advise you the dealer in your territory who gives this service.

Have YOU Tried The M.C.M. PHOTOMETER

THE Enlarging Exposure Meter

WHAT IT DOES

e Tells you exactly how long to expose every enlargement

e Tells you what contrast grade of paper to use with each negative

e Tells you accurately the density scale of any negative

e Lets you turn out Nor-mat Full Scale, Low Key or High Key prints as you desire

e Gives you an accurate iight standard on which to base your judgment for special effects, dodging, printing, etc.

e Can be used with any size enlarger

No tables or charts to refer to—reads directly in minutes and seconds

Will maintain its calibration and last indefinitely (The G E bulbused is burned at less than one third its normal watt-

It is now in daily use in thousands of dark rooms throughout the world. Ask any one of these users what they think of it. Ask them if it is saving them Money? Ask them if it has improved the Quality of their work—if it is saving them Time? Ask them if it Really Does do the many things we claim for it? We know the answers-Your Dealer knows them, but-

ASK THE MAN WHO USES ONE!

Send for free circular describing this remarkable new accessory. If your Dealer cannot supply you we will ship direct on 10-day money back trial basis (and no questions asked on \$4.85 receipt of

PHOTOGRAPHIC enlargement 64 A inches high and 50 inches wide made from a mere 35-mm negative and showing an Indian chief will soon become a familiar figure throughout the country as the Zeiss exhibits make their rounds. The negative 18 the work of Frank H. Shearer, of Bay City, Michigan, who writes that the negative shows "no perceptible grain" when blown up to these dimensions, "and every detail is perfect." He adds that no "step up" process was used, that is, no intermediate negative, and that the enlargement was made directly from the original 35-mm negative on paper 50 inches wide, not pieced together Mr. Shearer gives the following data. Exposure in Contax III, equipped with Sonnar f/2, at f/4 and 1/125 second Film used was Eastman Panatomic and development was in MPC

HUNTING WITH FLASH Guns

THE Craighead brothers, Frank and I John, who have been doing some notable work in the field of wild bird photography, pay tribute to the range finder and the flash gun for having made possible some unusual shots which they say could not otherwise have been obtained. Among the pictures which they have made are the two which they kindly permitted us to reproduce here Concerning one of these they write.

'This represents an osprey or fish hawk leaving a fence post with a fish in his right talon. This picture illustrates how he uses one foot to shove off with and the other to grasp his prey. A few seconds later he will clutch the fish with both talons. Our Kalart

Amateur Photographers

New Ways in Photocaaphy, by Jacob Deschin. Eminently practical from every point of view, this new book contains nothing of theory and nothing that the advanced amateur photographer will not find valuable in one way or another. It covers the whole range of amateur photography, discussing such things as trick pho-tography, photomurals, retouching, infra-red, and a number of other subdivisions that will not be found elsewhere in as clear and concise a manner. \$2.90

INFRA-RED PHOTOGRAPHY, by S. O. Rawlings. A treatise on the use of pho-tographic plates and films sensitive to infra-red. Exposure and processing are fully covered; formulas are given for sensitizing. \$1.65.

UNIVERSAL PHOTO ALMANAC AND MAR-KET GUIDE. How, when and what to photograph in order to make money with your camera; where to sell different types of prints. \$1.00.

CAMERA LENSES, by Arthur W. Lockett. Explains simply and clearly, yet with scientific accuracy, all the underlying principles of lonses. \$1.10.

CHAMPLIN ON FINE GRAIN, by Harry Champlin. A complete hand-book on the entire subject of fine grain, including formulas and how to compound and use them. \$1.90.

PHOTOGRAPHIC HINTS AND GADGETS. by Fraprie and Jordan. How to make all kinds of photographic accessories from film clips to cameras to lighting equipment, and so on; 250 articles and nearly 500 illustrations. \$3.70.

ELEMENTARY PHOTOGRAPHY, by Neblette, Brehm, and Priest. You can learn much of the fundamentals of photography from this little book even though you have little or no knowledge of physics and chemistry.

PHOTOGRAPHIC ENLARGING, by Frank. lin I. Jordan, F. R. P. S. One of the most interesting and authentic books on enlarging. Its 224 pages cover every phase of the subject and 75 illustrations, many of them salon-winners, show the value of correct technique. \$3.70.

PORTRAIT PHOTOGRAPHY, by H. Williams. Fundamental principles of composition and lighting, paying the way to satisfactory results in this particular branch of photography.

"Annoyed"

focusing device made this picture possible,

for quick focusing was essential.
"The other picture," they continue, "was taken with the aid of both the focusing device and the synchronized flash. It represents a young great horned owl in its nest The nest was located in a small cave on the side of a cliff. The picture was taken as the young owl raised his wings in alarm. Even with the fastest film, it would have been impossible to get the picture without a synchronized flash. The great horned owl is one of the largest and fiercest of our owls, usually nesting in large wooded tracts far from the habitation of man."

CAMARADERIE OF THE

CAMERA

THE camera has become the passport to impromptu friendships to such an extent that it needs no more than the display of one's camera in park or street or aboard ship to strike up an acquaintance with any other camera toter in sight. This has happened to this department on several occasions. We would be poking the camera up at some building or other and before we had finished, someone would come up and want to know what stop and shutter speed were used, what film, what filter, and so on In no time at all the two would be talking on camera subjects in general with the freedom one usually employs with a friend of long standing This unfailing "open sesame" to acquaintanceships that characterizes the camera fraternity led this department to invent a new term, namely, "cameramour," and the camera user as "cameramorist" Camera love and camera lover seem a bit far-fetched when heard for the hrst time But how about bibliophile? Persons who collect first editions of books think this term to be quite proper and aptly descriptive of the book collector.

STANDARDIZING

PHO COGRAPHY

S TANDARDIZATION in the field of photography took another step forward recently with the appointment of a new committee on standardization, according to an announcement by the American Standards Association, of New York City. Initiated at the request of the International Standards Association, the new committee will represent 40 different organizations, including Federal government departments, user graups, manufacturers of photographic

platform returns to horizontal position again, this see-saw movement continuing throughout the development period. Water flow regulation adjusts speed of agitation. Adjustable platform takes all standard tanks

5 by 7 Two-Pellicle One-Shot Aluminum Casting (\$100). Intended to serve as body around which one-shot color camera may be built and assembled. Castings declared to be correct in design, rugged in shape and fully machined so that all important surfaces are accurately flat. Distributors ay anyone with some shop experience can quickly build the rest of the camera. Those interested in building the camera may obtain photograph of the casting with further information from this department Ask for "Photograph 100" and supplemental data"

Photo Rissia (\$1) For washing prints Changes water and moves prints in fresh water automatically, reducing washing time

30 to 50 percent, according to manufacturers' claims. Device is merely set under faucet and water turned on, allowing small stream to strike pan When one side has been filled with water, it becomes heavy and tips, thus

permitting other side to receive stream Water continually runs out through slots. Thus rocking back and forth, several 5 by 7 inch (or smaller) prints may be washed at same time. Pan 1½ inches deep, made of heavy steel coated with special asphaltam paint to resist acid.

KODAK TABLE TOP THEOD (\$7, complete with Pan-a pod and Tilt a-pod). Camera support for table top-photography, still-

lifes, and so on Used on table, chair, floor or other convenient support Legs, sturdy and without joints, unscrew from solid metal head so outfit can be carried in pocket. Leg spread 9½ mehes, height 7 inches. Each leg

rubber-tipped, non-skid, will not scratch or mar polished surfaces. Pan-a-pod (\$3) is revolving head for use on any tripod with standard screw. Insures smooth, easy swing in either direction when panoraming with still or movie camera. Degree markings help in making "panoramia" pictures with still camera. Almost full circle may be pictured, locking screw holding center of Pan-a-pod head at any selected setting. Tilt-a-pod (\$2.50) is adjustable camera support permitting tilting to any desired angle, Tripod alone \$1.75.

Liff-Master (\$9.75). Transforms any ordinary household electric light bulb into flood light giving up to five times normal brilliancy. Lite-Master connection cord is plugged into any 110-volt A C. outlet. Lights to be controlled are then plugged into outlets provided on the Lite-Master. Regular

JACOB DESCHIN, conductor of our "Camera Angles" department, will answer in these columns questions of general interest to amateur photographers. If an answer is desired by mail, enclose a stamped, addressed envelope. Queries should be specific, but Mr. Deschin cannot undertake to draw comparisons between manufactured products nor to advise on the purchase of equipment or materials -The Editor.

O. I am interested in making my miniature films into positives for projection. I understand there is a special formula used. There is a way to make lantern slides, but I wish to develop the film as motion picture film is developed. Would you tell me the formula and process of development?-W. R.

A. The better method of obtaining positives from your miniature negatives is to print on positive film and use the latter for projection. However, here is one good reversal process that may be employed in this connection. Several others are given in the "Universal Photo Almanac and Market Guide.

Soak the film in water at 65 to 70 degrees, Fahrenheit, for one minute and follow this by development for three to five minutes until all highlights in the negative image are as dark on the back side of the film as on the emulsion side. This developer is made up of one part of the following stock solution and one part water, temperature in each case being 65 to 70 degrees:

Stock Solution

Water (at 125°)	1 gallon
Metol	180 grains
Hydroquinone	1% ounces
Sodium sulphite (desiccated)	7 ounces
Potassium bromide	1/4 ounce

Add one dram of strong ammonia water to each 16 ounces of working solution.

After development, immerse for three minutes in combination stop and hardening bath made up of one ounce of chrome alum to each 32 ounces of water. For another three minutes bleach the negative image out completely in the following bleach bath.

Water 32 ounces Potassium bichromate . 64 grains Sulfuric acid (concen. pure) 4 drams (Note: add the acid to the water, not the

Now wash for three minutes and then clear out stain of the bleach solution in the following clearing bath for 2 minutes:

32 ounces . 1/2 ounce Sodium bisulphite

Turn on the white lights, A general service 100-watt damp, five feet from the film, will be about right. Weeh film for five minutes in running water, or six changes of water. Finally, redevelop film in the same developer used the first time, or any good non-staining M-Q formula, such as DK-50, D-16, or D-72, diluted 1 to 4.

O. I have heard there is a way of drying glossy prints within a few minutes time. Can you describe this method? -S. M.

A. Fill a tray with wood alcohol. Before placing on the ferrotype tin, immerse the thoroughly washed print in the alcohol for one minute. In less than five minutes the prints will peel off the tins, completely dry.

O. Please list some of the advantages and disadvantages of the "vest pocket" (1 1 by 2 1 4") vs. the square (2 1 4") by 2 1 4") negative sizes.—L. A. K.

A. The square negative has become very popular largely because of the fact that the camera does not have to be shifted to make vertical shots, as one has to do in the case of the rectangular shaped negatives. Many, however, avoid this shifting by making all shots in the normal position and enlarging to the desired composition. On the other hand, the square negative is disliked by some because most pictures are enlarged to a rectangle, whether vertical or horizontal, and one is inclined to forget and to compose the subject in the view finder or ground glass so that nothing looks right but the square composition. The main answer is, so what? Many pictures are made in the square format and look good that way. There is no law against square pictures and if your picture looks better square than rectangular, go ahead and print it that way.

O. In comparing the readings afforded by my xxxxxx electric exposure meter with those given, under the same conditions, by an electric meter owned by a friend, I found that my meter called for exposures about twice those indicated by the other meter. Whose readings are correct, mine or his?-D. J. L.

A. Assuming that both meters are in good working order, we offer the opinion that it is not correct scientific procedure to take two meters and compare their readings, condemning any differences that may appear. This is due to the fact that different meters

FOTH DERBY

STILL THE BEST BUY in the

MINIATURE CAMERA FIELD with an f/2.5

ANASTIGMAT LENS

-only \$33.50

These are exceptionally fine miniatures for their surprisingly low prices They are of precise and quality construction, throughout, yet amazingly light and compact. And now for the first time in many months, the manufacturer is able to keep pace with the demand.

The Foth-Derby cameras are equipped with the latest type delayed-action focal plane shutters with speeds from 1/25 to 1/500 second, large magnifying tube-sight view finders and have many other features, including front lens focusing up to 3½ feet You get 16 pictures, half VP size (1¼ x 15%) on a roll of standard VP film

Dimensions: $4\frac{1}{4} \times 2\frac{1}{4} \times 1\frac{1}{8}$ inches Weight Only 12 ounces

The unique combination of quality, performance, appearance and price which distinguishes the VOGUE is directly due to the large scale production methods of the Coronet factory Miniature Photography with its new and entrancing method of candid picture making—until recently the fad of the wealthy—is now within the means of the average purse. A pleased purchaser writes 'I have recently become the proud possessor of a Vogue Camera As an amateur I have taken some grand little pictures which I think could not be bettered with a more expensive camera. I think its performance is equal to any expensive camera obtainable "We are quite willing to let you convince yourself and are giad to extend to vou the Co D Orders privilege of 10 days' trial.

Dept 75

The WHITESTONE COMPANY

The WHITESTONE COMPANY WHITESTONE, L. I. NEW YORK

calibrated differently, all providing readings that will result in negatives of good density, though differing as to the depth of this density. That is, one will result in a negative of a certain density while another will have a somewhat greater degree of density. The printing results, however, will be about the same. As a matter of fact, due to the great latitude of modern emulsions, it is possible to over- or underexpose to a considerable extent without injuring the printing possibilities of negatives so exposed.

Therefore, it is possible that the readings of both your meter and that of your friend were correct for the subject in question. Also, it must not be overlooked that exposure meter readings are not intended to be the last word concerning exposure, but to perform the services of a guide That is, if you do not like the density provided by the meter reading, all you need to do is to give particular films a higher or a lower rating than that indicated for the particular

Q. What is the proper height for an enlarging table?—M. S.

A The ordinary table height of 30 inches will do, but if you are constructing a table specifically for the purpose, we would suggest reducing this to about 26 or 27 inches This height will be found more convenient for persons of average height. Taller persons on the other hand, may find that a height greater even than 30 inches may be more suitable

Q. Would you please explain the presence of bubbles in my lens, as well as their effect? There seem to be more bubbles in my lens than in other lenses I have seen,-D. L.

A These bubbles are common with all lenses and are unavoidable in the manufacture of lenses. Furthermore, it is of little consequence whether your lens has more bubbles in it than, perhaps, another lens von may compare with it. The bubbles are absolutely transparent and do not affect the clarity or sharpness of the image in the least. The light image passes these bubbles practically without alteration and with the same ease and directness as if the bubbles did not exist

O. How should the condensing lenses be mounted in an enlarger—flat surfaces together, or convex surfaces together? When I make enlargements of about 4 diameters magnification the prints show marks of air bubbles from the condenser lenses, and also a dim shadow from one side of the bulb I use for enlarging (a 75-watt frosted Maz-With greater magnifications around 7 diameters, these defects are not noticeable in the prints.-- K. L. R.

A Answering your first question, condensing lenses are mounted with convex surfaces facing each other but not in contact The result of mounting these lenses in this fashion is to concentrate the light rays, make them converge, whereas the opposite would be the effect were the lenses mounted with flat surfaces against each other. It is not possible that the air bubbles will appear as marks on the prints for the reasons outlined in our reply to D. L. elsewhere in this department. More likely, the marks you refer to are caused by lint or dirt

on the condenser. Clean your condenser lenses carefully, as well as the surfaces of the negatives, and observe the difference. The shadow you refer to is doubtless due to the fact that the enlarging light is not properly centered, an absolute essential for obtaining an even disk of illumination over the negative area.

Q. In focusing on the ground glass of my miniature single-lens reflex camera, the smaller the stop the more difficult the alignment becomes. I would appreciate it if you could help me with some suggestion.—D. W

A. Here is an idea that has been tried out with success by a man who uses one of these miniature reflex cameras in photographing architectural details on buildings You know those transparent rulers they sell at the five-and-ten-cent store? This man cut a piece from one of these rulers about a half inch square and glued it in the center of the ground glass. The thin criss-cross lines are a great help in alignment, particularly when the lens diaphragm is stopped down or where the light is poor and focus ing is difficult even at the larger stops

Q. I wish to construct a depth-of-field table for my camera lens with the help of the instructions given by you in the July, 1938, issue. My camera is an Agfa Isolar, 9 by 12 cm size. Its lens is f/4.5and is marked as equivalent to 13.5 cm in focal length. I think I should be able to prepare the required table by following your suggestions in the July issue provided I know the circle of confusion. I would like to know how this is determined.—C. R.

A In our reply to P. P. A. in the September, 1938, issue, we attempted to explain this subject and if you have not seen this, perhaps reference to it may help you to understand the matter a little better. Generally speaking, the diameter of the circle of confusion which one elects to employ in figuring out a depth-of field table for a particular lens depends on two things, the distance from which the picture is to be viewed and the degree of enlargement to which the negative is to be subjected. The greater the distance from which the picture is to be viewed or the smaller the enlargement of the negative, the larger, relatively, is the permissible circle of confusion. The reverse, however, obtains when the viewing distance is relatively closer or the enlargement is relatively greater. In your particular case, a circle of confusion of 1/250 will be right since 8- by 10- or 11- by 14-inch enlargements are probably the largest you intend to make. if you intend to make any enlargements at all, and a viewing distance of about 10 or 12 inches will be the closest approach.

O. Please advise what can be done to remove the film of moisture or dust that sometimes settles on the mirror of my miniature reflex camera when the lens is removed or changed .-- W. P. M.

A. It is our suggestion that when you remove the lens from the camera you take extra precautions against the possibility of dust or moisture entering the camera and settling on the mirror. Once dust has settled on the mirror, however, our best suggestion is that you attempt to remove this dust with a very soft brush or cloth, being careful not to press heavily on the mirror in doing so.

YOU CAN SLEEP WELL

By Edmund Jacobson, M.D.

YOU can take it from an editor who has tried many systems of overcoming sleep-lessness: If you read this book through and follow the directions given, you will not only go off to sleep quickly, but you will sleep restfully. (269 pages, 6 by 8½, well illustrated)—\$2.10 postpaid.—F. D. M

LIGHTING IDEAS IN PHOTOGRAPHY

By William Herrschaft and Jacob Deschin

LIGHTING is the backbone of all photog raphy. Without lighting, photography is impossible; without proper attention to the problem of lighting, good photography is impossible. In this compact book the authors have treated the entire subject of artificial lighting in photography and have given descriptions of various methods of achieving certain desirable lighting effects. Light sources and controls are discussed in detail and instructions are given for making light ing outfits. Here in one book is compressed all that the serious-minded amateur photographer needs to know about the art of artificial lighting. Co-author Deschin is the conductor of the "Camera Angles" department in Scientific American (276 pages, 6 by 812 inches, numerous photographs and line draw ings 1 -- \$2.85 poetpaid -- A P P

GIANT FISHES, WHALES & DOLPHINS

By J. R. Norman and F. C. Fraser, both of the Department of Zoology, British Museum

A SOI ND, solid, scientific reference book on the many varieties of larger fishes (sharks, rays, barracudas, remoras, and so on) and the cetaceans such as right whales, fin whales, sperm whales, porpoises, and dolphins, which are likely to be seen on pleasure cruises and voyages, each discussed in form comprehensible to the layman. The illustrations, many of them in natural color on fine paper, are excellent. A handsomely produced volume of permanent value. (361 pages, 5½ by 8½ inches, 97 illustrations and eight color plates each showing several fishes)—\$4.10 postpaid—A. G. I.

AUDELS NEW AUTOMOBILE GUIDE

By Frank D. Graham

PREPARED particularly for automobile owners, mechanics, and service men, this compact book gives a vast amount of information regarding the various parts of automobiles, their care and replacement (1500)

TRAINING YOUR DOG

By Carl Spitz

W HAT man has not wished for just such a concise, well-illustrated book which would tell him the best workable methods of training his "best friend"? This author has done an excellent job in the space of 234 pages and has supplied numerous illustrations to show habits to be broken and how they are broken We can recommend this to any dog lover. (In an attractive paper binding -512 by 814 inches) -\$2 60 postpaid - F. D. M.

THE LEICA BOOK IN COLOR

By Anton I Baumann and other contributors

ORE than 70 reproductions of color prints made with the Leica camera on Kodachrome film by Anton F. Baumann are the basis of this fine book the principal aim of which is to demonstrate that "pho tography in colors has become accessible to every amateur" Edited by Kurt Peter Karfeld and translated by H. W. Zieler from the German edition of this work, the book in cludes, besides the well reproduced color pictures and notes explaining how each one was made, chapters by Dr. Hans A Kluge on "Fifteen Minutes of Theory About Colors and Color Photography" and "From the Color Transparency to the Book Print in Color", hy Dr Otto Croy on "The New Agfa Color Film", by M. McMaster on "Color Prints by the Eastman 'Wash-Off Rehef Process'"; and by Mr. Baumann on "Taking Color Pictures." (48 pages of text, 90 illustrations and charts in colors.) -\$4 60 postpaid -- J D

REFURBISHING THE HOME

By Carl G. B. Knauff

Home workshop enthusiasts will find here eminently practical instructions for repairing and refinishing furniture, as well as doing other jobs that will help to make the home more livable. Included are suggestions for interior decoration and for the arrangement of furniture to give the best possible effect with the space and materials available. Painting, wall coverings, rugs and carpets, furniture styles, pictures and decorative accessories, are some of the other phases which are thoroughly covered in an

understandable manner. (338 pages, 6½ by 9½ inches, numerous photographs and drawings.)—\$2.85 postpaid.—A. P. P.

THE LIFE STORY OF THE FISH

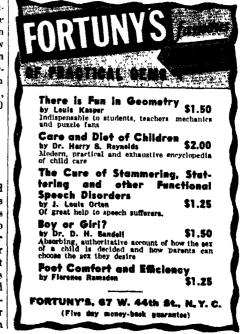

By Brian Curtis, State of California Division of Fish and Game

FOR those fishermen (and others) who have scientific curiosity about things in general and fish in particular this is the book, and it provides evidence that there is a lot more science in one poor fish than some other poor fish who merely fish may realize. What a fish is, body covering, framework, senses and nervous system (some surprises here), air-bladder, internal workings, reproduction, growth, trout and salmon, other game fishes, habits and adaptations-those are the chapter headings and the approach is scientific without being too scientific, and is always friendly, informal, and readable, not pedantic or stuffy. Many common questions such as "Do fish feel pain?" are answered (260 pages, 51/2 by 8 inches, 38 illustrations)-\$3 10 postpaid -A G I

THE MAGIC WAND OF SCIENCE

By Eugene W Nelson

POPULARIZED science is the keynote of this book, but not in the sense that an attempt is made to sensationalize and play up those aspects of science which approach the borderline of pseudo-science. The author has written particularly for the intelligent layman who has a definite desire to acquire a certain amount of knowledge regarding science, and who does not wish to delve deeply into the background. The text runs the gamut from microscopy to motion pictures, from soy beans to the fourth dimension, from enzymes to lightning; it covers briefly a wide field of interesting things in between. (213 pages, 5½ by 8 inches, 45 illustrations)—\$2 10 postpaid—A. P. P

A Monthly Department for the Amateur Telescope Maker

Conducted by ALBERT G. INGALLS

LUMINIZING one's own telescope mir-A rors is probably uneconomical, considering the time, materials, and cash required to build the rather elaborate appaiatus. On the other hand, the man who rationalizes his decision to build it as "an economy," but is subconsciously simply seeking something that is fun to do, is a real living demonstration of Professor Hale's characterization of the amateur-a man who "works because he cannot help it" He is therefore altogether in order, or better Guy R. Evans, 3007 N. E. Flanders St., Portland, Oregon, submits a description of a vacuum pump he has made and used in connection with Prof. Yeagley's aluminizing equipment described here in July and August, 1937, and he says it "gives better results than I ever thought would be possible" He made this diffusion pump because he did not find that the mechanical pump there recommended gave a good enough vacuum. Here is his description

"The pump, shown in Figure 1, is constructed almost entirely of brass and copper tubing at least 1/18" thick (do not use cast metals). The end pieces for boiler and jet chamber are 3/16" sheet brass The water jacket 5 may be 1/32" brass tubing.

'There are two stages in this pump. The first, or jet, stage is in the upper part, and the second, or annular, stage is located just below. The clearance of the first stage jet depends upon the fore vacuum, and should be adjusted to about 1/2". Most oils cool readily, so the heavy-walled copper tube 2 is insulated by a glass tube 10. Tube 2 rests on the bottom of the boiler, and is adjusted by a 1/4" cap screw 1. The jets are shaped m such a way that they will not clog with oil. This has been a serious defect of most oil pumps.

'Il is a pin for removing tube 2. It can be lifted out with a hooked wire.

"9 18 soldered to the tube that comes from the boiler, and acts as a guide as well as a jet The openings in this jet should have approximately the area of the copper tube.

"A "' length of tubing is soldered to 9. This centers the glass insulating tube 10, so that when the copper tube is removed, the insulating tube will remain in place

"7 is a glass insulating tube to insulate 8. "The openings marked B serve as passages for the oil vapor to the first stage jet

"15 is a copper spinning with a 1/2" hole in its center for the copper tube 2 to pass through. This part of the jet should be accurately centered and soldered in place.

'14 is a trap to let the condensed oil pass back to the boiler without letting the air and vapor through 'this trap resembles the trap on a sink

"13 is a 1/4" strip of brass that carries the oil to the wall of the pump

"16 is the return tube to the boiler.

"Joints marked A, in boiler and connecting tubes, also 8 and 16, are silver soldered or brazed. Other joints may be soft soldered

"The cover, 6, shown in detail, sets in a seat and is waxed in

"The detail of 8 shows a section of the

top of the boiler, also the tube that connects the boiler with the jet chamber. This piece, also the ends for the boiler, jet chamber and water jacket, should be turned in a lathe

"5 is the water jacket that surrounds the jet chamber. It has two short lengths of 1/4" pipe. The water intake should be at the bottom, to prevent trapping.

"The boiler is made of telescope tubing slid into the outer casing. All joints in the

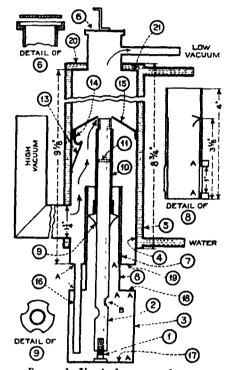

Figure 1. Vertical section of pump

boiler should be silver soldered and then turned in a lathe, so that it can be slid into

"When you have completed the pump, connect to a Cenco-Hyvac or equivalent Make as short connections as possible, especially from oil pump to vacuum chamber. Fill boiler about half full of Apiezon oil 'B'. Place cover on pump and seal with wax. Dr. Strong's mixture, as described in 'ATMA' is O.K. Start the fore pump and scout for leaks. If none is present you should have a high enough vacuum in 15 minutes (using a 9" bell) to start the diffusion pump.

"Heat may be applied to the boiler by a hunsen burner or electric plate. Care should be taken not to overheat. You can tell when the pump is too hot by placing your hand on the high vacuum pipe that goes to the bell, this pipe should be just warm about 3" from the pump. In a short time you will notice the discharge rapidly getting lighter (for this pump works rather fast), until it finally goes out with a clean-up voltage of about 10,000 or 12,000 volts. A neon sign transformer may be used. Let the pump run for 10 or 15 minutes longer, to be sure the vacuum is O.K. Then fire your aluminum. When the coat is thick enough, turn the heat off, but do not stop the fore pump until

the diffusion pump has cooled enough to let the oil condense. Then shut down the fore pump and open the air valve to the vacuum chamber. The articles in the July and August, 1937, issues of the Scientific American take you through these steps very thoroughly.

"With this set-up I have aluminized in 17 minutes, although I generally allow 30 minutes. The resulting coats are beautiful-far better than any silvering I have ever done.

"List of materials:

12" of 21/2" inside diameter brass tubing 1/10" thick or thicker

9" of 3" inside diameter brass tubing 1/22" thick for water jacket.

12" of 11/4" inside diameter brass tubing 1/16" thick.

1" of %" inside diameter brass tubing 1/2" thick.

About 11/2" of 11/4" diameter cold rolled brass for 2nd stage jet.

31/2" of 1/4" inside diameter copper tubing. 9" of 1/2" outside diameter copper tubing. I short piece of copper tubing 1/8" inside diameter for 14.

Enough sheet brass 1/16" thick, for ends of boiler, jet chambers, 17, 18, 19, 20, and

Enough sheet copper 1/32" thick to complete first jet.

1 ¼" by 1" cap-screw. 3½" of ½" inside diameter glass tube for 10.

3" of 11%" inside diameter glass tube for 7. "The Apiezon oil can be obtained from the J. G. Biddle Co., Philadelphia, Pa."

THE above description was submitted to 1 Dr. John Strong, who suggested that the reader also see the Review of Scientific Instruments, Vol. 6 (1935), page 66, describing a similar pump, and the same, page 75, describing another approved design. He mentioned that a good up-jet design that is simple to build would soon appear in a book he was writing. He found some minor faults with Evans' pump, just described, but, on the whole, commended his enterprise. This book, "Procedures in Experimental Physics," has subsequently appeared and it contains a 57-page chapter on the technique of high vacuum, with another chapter on evaporating. These cover this subject of aluminizing with more thoroughness than anything thus far made available anywhere, and in a wholly practical manner; in fact, anyone contemplating the construction of an aluminizing apparatus would probably miss more tricks than one if he did not first learn what is in this new book by the leading authority on this work.

N the September number F. M. Garland. L of Pittsburgh, told how he made a strain tester for glass, using a lamp in a box, a ground glass screen and polarizing eyeglasses. Just after we inserted that note we espied an advertisement for the kind of equipment which the Polaroid Corporation makes up as a stock product for inspecting glass containers, tubing, tableware, and so on-that is, doing essentially the same thing

as Garland-and asked them for a photo. This is reproduced in Figure 2, merely to show how the professional makes up the same general elements into a stock product. In their reply, the Polaroid people referred to Garland's rig as "ingenious." They also sent a sample of Polaroid Type I for reducing the apparent brightness of the night sky. "The light from city lamps reflected from particles in the air is often so strongly polarized," they state, "that our friends from Harvard tell us it is possible to get rid of a great deal of this light by making the observation through Polaroid, rotating the

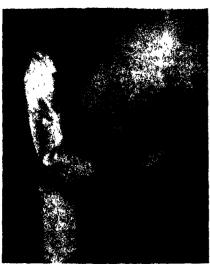

Figure 2: Commercial strain tester

Polaroid till the darkest condition is obtained. This reduces the intensity of the celestial object but it reduces the stray illumination to a very much greater degree and so increases the contrast.

PAVORITE pitch lap mixtures of outstanding professional workers.

Of D. O. Hendrix, Mt. Wilson optical shops: Coal tar pitch, melting point 170, 2 lbs., Mefford Chemical Co., 1026 Santa Fe Ave., Los Angeles, Calif. Pine tar oil (drug store), amount depending on hardness of the pitch; start with 2 liquid oz. and increase Judiciously toward 4 oz., if needed in order to bring to desired hardness. To these add 11/2 oz. beeswax. In addition, the lap is given a thin coating of beeswax, not alone to eliminate sleeks and scratches due to grit but to reduce polishing friction. Prof. John Strong, in his book "Procedures in Laboratory Physics," mentioned above, includes a 60page account of Hendrix' methods of working optical surfaces, which will intrigue advanced workers. We amateurs are plainly not so far behind, but there are things we

of M. H. Brown, optical shops of the California Institute of Technology, for general use, including work on the 200" mirror: Resin, 1000 grams (about 2 lbs.). S. A. E. Penn Oil No. 30, 4 oz. paraffin, amount depending on need; start with 75 grams (about 21/2 oz.) and increase judiciously toward 150 grams. Do not paint the paraffin on top.

As the reader will readily understand, so much special work engages the attention of these two men at present, pressing for com-pletion on schedule, that, against their inclinations, they will hardly find it possible to answer inquiries such as persons mentioned in these columns usually receive in considerable numbers.

THE BEGINNER'S CORNER

S OMETIMES the unsuspecting tyro telescope maker endeavors to economize by purchasing low-priced rouge. Some have even used jeweler's rouge from their local shops Trouble often followed, which the beginner, without previous experience by which to judge, regarded as unavoidable. There is rouge, and rouge; yes, there is even rouge and rouge, and rouge Polishing silverware (jeweler's rouge) doesn't require anything fancy—thus would be just a waste of money. Polishing eyeglasses requires much better but not the finest; the latter would therefore he a needless expense. Third standard of work, precision optics (including telescope work) requires real Rolls-Rovce rouge, but even that grade is inexpensive

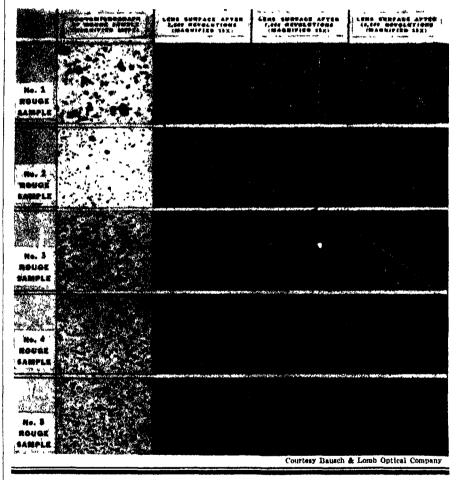

The photomicrographs shown below tell us something about rouge, and rouge, and rouge. Each horizontal row reveals the magnified

surface of a lens which has rotated on a spindie under a different grade of rouge. This is machine work, it is true, but the findings apply equally to the amateur's hand work. Top row shows a rouge that would be very decidedly unsatisfactory. Each row below shows a better grade and the effects thereof. Only No. 5 (B. and L. 358-52738) is suitable for precision work.

Now you have an idea, thanks to these high magnification close-ups, about the great differences between rouges. Yet they all look alike when seen at the bottom of the parcel they come in.

It is worth while to go back and study the same photomicrographs again by vertical columns, comparing each. In the first column especially, note the bad but increasingly better particle size distribution. Study also the pitting effects of each, in photomicrographs to the right (pits shown by little white dots)

As stated in the manual of the telescope making hobby, "Amateur Telescope Making," the particles of rouge are roughly 1 30,000 to 1/50,000 inch in diameter—that is, for good rouge

TELESCOPTICS

(Continued from preceding page)

In The Journal of the American Ceramic Society, 2525 High Street, Columbus, Ohio, Vol. 20, No. 2, appeared an article entitled "The Scratch-resisting Power of Glass and its Measurement," by James Bailey of the Hamburg, N. Y., firm of Bailey and Shaipe (now the Optical Glass Products, Inc., by the way). The following paragraphs, quoted from this article, throw an interesting sidelight on borosilicate and other glasses, and complement our discussion of

glass, begun in this department last month

"If one piece of glass is scratched by drawing across it the corner of another piece, the contact area is small and the unit pressure is comparatively high. When the corner moves rapidly, the work done in overcoming friction easily generates sufficient heat to raise the temperature of the sliding corner above the softening point of the glass; the sliding corner, moreover, becomes so highly heated that it produces a streak of light readily visible in the dark.

"This beating effect brings into the scratching process a new factor, namely, the fusibility of the moving point. Thus a piece of

quartz glass, though softer than ordinary window glass, will easily produce a long, deeply cracked scratch in a piece of window glass when drawn rapidly across it, because the rubbing corner remains hard at the temperature attained. A glass corner will not scratch the quartz slab under the same conditions because it softens and loses its sharpness almost at once. It is possible, however, to make a deep crack and scratch on the fused quartz with the corner of a piece of window glass by keeping the rubbing velocity at a very low figure, such as one milli-meter per second or less. In this connection, all the common abrasives such as sand, corundum, silicon carbide, and emery have very high melting points, while diamond, the hardest of all, is infusible.

"Grinding experiments show that quartz glass and glass containing large amounts of silica and B.O. are the most difficult to grind The ball test shows that these types are really softer than most other glasses. The reason for this is apparent if a fresh scratch made with a diamond is observed under a micro scope. The scratch in quartz glass, once made, undergoes almost no change. The initial fractures do not extend nor does any appreciable amount of material fly out of the scratch. The same applies to a considerable extent in the case of high B.O. glasses. With glasses of the conventional window-glass and bottle types, the initial scratch is small, but pieces begin to fly out of the body of the glass along the sides of the scratch almost at once, and this process continues for a period of several minutes, at the end of which time vastly more glass has been loosened than was initially cracked or apparently injured by the scratch. The ability of a material to resist abrasion, as in grinding, is a measure of its work-absorbing power rather than its true hardness."

NOMOGRAPHS is the name given by their "worker-out," G. W. Gasper, 3245 Woodford Rd., Cincinnati, O, to six 12" blueprint wall charts on each of which a required datum can be found simply by placing a straight edge through two known values inscribed along a line and then looking for its intersection with a third line, hence the term almement charts, also applied to them. For example Given mirror diameter and focal ratio, automatically find accuracy required in parabolization; or given diameter of eyepiece field lens and focal length of objective, find angular field of view, or given mirror diameter and f.l., find parabolization depth. Similar charts are for exit pupil, for diagonals and for compound reflectors. Not merely a lot of arithmetical slavery saved but the designer can swing a straightedge up and down the lines and visually arrive at his optimum condition, also getting more closely acquainted with the whole gamut. For these charts Gasper asks about a quarter of what might be charged; evidently it's a labor of love. He is a member of the Amateur Telescope Makers of Cincinnati.

SOLICITUDE—or something. Professional optical manufacturer who has evidently just heard of amateur telescope making hobby writes that he learns that amateurs in it "attempt to grind and polish their mirrors themselves," and kindly offers to "prepare to produce these mirrors in quantity." A medal will be awarded to the amateur who submits the most suitable reply (on asbestos) to this optical illusion. "Attempt." Gritiral

TRADE MARKS AND UNFAIR COMPETITION

By ORSON D. MUNN

A TRADE MARK is an intangible asset of a business, yet its actual value may grow so large that it becomes the very foundation on which depends the whole structure of the business. Because of this fact, every business man should have available such information on trade marks as will enable him to judge with a fair degree of accuracy the desirability of any mark which he may be considering

Here, in one handy volume, written in non-legal terms, is a simple yet comprehensive interpretation of the Federal statutes and the body of common law relating to trade marks and unfair competition.

Price \$1.00 postpaid

CERRENT BULLLEIN BRIFFS

(The Editor will appreciate it if you will mention Scientific American when writing for any of the publications listed below)

SMALL HOME BUILDERS' YEAR BOOK—1938-1939 is a 64-page symposium of attractive information on designing, financing, constructing, equipping, decorating, and furnishing a home. The articles are thoroughly illustrated and several interesting plans of small homes are presented. Every home owner will find something of interest here. National Small Homes Bureau, Inc., 572 Madison Avenue, New York City.—25 cents.

Chologic Map of California is a sixcolored, lithographed wall map 6½ by 7½ feet, sent in six sections, indicating in detail the general geology of that state Division of Mines, State of California, Ferry Building, San Francisco, California.—\$4.00.

THE SCOTTISH INDUSTRIAL ESTATE is a 24-page illustrated booklet that tells of the industrial advantages of the Estate at Hillington, near Glasgow. This Estate exists to alleviate unemployment by offering industrial facilities to attract new industries and branches of existing industries to this area of Scotland. Scottish Industrial Estates Limited, 29 St. Vincent Place, Glasgow, C. 1, Scotland—Gratis.

OPERATORS HANDBOOK deals specifically with truck, bus, and farm and industrial tractor tires, presenting statistical material of interest to every operator of such vehicles. Particular attention is paid to truck-tire failures, including the heat-speed problem. Pocketsize, 68 pages. The B. F. Goodrich Company, Akron, Ohio.—Gratis.

Some Common Fallacies about Wood brings out many interesting facts regarding various types of woods found in the United States. For example: Wood does not necessarily decay with age. Decay is caused by the attack of a fungus. Request Mimeograph R1167. Forest Products Laboratory, Madison, Wisconsin.—Grans

THE EARLY HISTORY OF AIR TRANSPORTATION, by Edward Pearson Warner, is a 74 page booklet based upon a James Jackson Cabot Professorship lecture. It has been prepared in an attempt to reconstruct the atmosphere of significant periods in the development of aeronautics and to suggest historical implications and the influence on the future of the more significant events. A brief bibliographical appendix gives valuable references to source material. Norwich University, Northfield, Vermont.—50 cents.

What's What in Rayon is a 22-page booklet that tells in question and answer form everything that the average user of rayon could possibly want to know about the fabric. For example: What is spun rayon yarn?; How has rayon contributed interesting color effects in fabrics?; In what price ranges are rayon fabrics found?; Do they stretch?; Will they wash?; Will they shrink? Rayon Division, E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela-ware.—Gratis.

THE PROBLEMS OF A CHANGING POPULATION is a 306-page book containing a report of the National Resources Committee concerning some of the major problems of our human resources. Data is presented in regard to population trends, anticipated stable population, changing age groups, migration within the country, health, education, economic opportunity, and so on. Government Printing Office, Washington, D. C.—75 cents (coin).

THE STORY OF WESTERN ELECTRIC is a 32-page thoroughly illustrated pamphlet that tells of the work which has made possible the highly efficient telephone system that exists today. This service of supply for the Bell System is a gigantic, highly organized institution that has contributed largely to efficient as well as low cost telephone service. Western Electric Company, 195 Broadway, New York City.—Gratis.

RADIO TROUBLE-SHOOTER'S HANDBOOK, by Alfred A. Ghirardi, has been prepared to cover every phase of radio repair service. It contains hundreds of pages of tabulated job data condensed and tabulated for easy reference. A large number of charts and tables will aid the service man in his work. Radio will aid the service man in his work. Radio & Technical Publishing Company, Department 35, 45 Astor Place, New York City—\$3.00. Illustrated circular free.

MICROSCOPE EQUIPMENT FOR THE AMATEUR is a 24-page pocket-size booklet that deals with microscopy as a personal hobby. It shows some interesting photo-micrographs and describes and illustrates various types of microscopes and other equipment that will aid in the pursuit of the hobby. Bausch & Lomb Optical Company, Rochester, New York.—Gratis.

Photography by Polarized Light discusses various types of Pola-Screens, describes the effects produced by their use, and illustrates these effects by drawings and photographs. Discusses exposure time, filters, accessories and negative materials to be used when employing Pola-Screens. Eastman Kodak Company, Rochester, New York, or photographic stores.—50 cents.

Radio Foto Loc, edited by Samuel Kaufman, contains 32 pages of information for radio listeners. It gives tuning data on American and foreign stations and presents 151 photographs of prominent radio stars. Recent advances in television are also covered. At your radio dealers or from National Union Radio Corporation, 57 State Street, Newark, New Jersey.—15 cents

IMPROVING THE FARM ENVIRONMENT FOR WILD LIFE is a 62-page illustrated booklet which shows how the farmer can best provide for the small birds and animals that live on his farm, with a minimum of trouble and expense and a maximum of return on the investment. Farmers' Bulletin No. 1719. Superintendent of Documents, Washington, D. C.—5 cents (coin).

CONTINUED FROM OTHER SIDE

of-the-month our judges choose Nor—this is another frequent misunderstanding—are you obliged to buy a book every month.

All important new books are very carefully reported upon. As a member, at your pleasure, you can do one of three things in any month-order the book of-the-month, order some other new book you are particularly anxious not to miss (you would be charged only the regular retail price, plus postage), or, instruct the Club not to send you any book at all. Your only obligation is to buy four books a year from the Club, if all four were books-of-the-month you would receive, in addition, two book-dividends

You Pay No Fixed Sum Yearly

In short, all the marked economies and conveniences which the Book-of-the-Month Club provides cost you nothing. There are no fees for joining, and you pay no fixed sum per year. You simply pay for each book as you get it—and you pay nothing more!

Moreover, you are neither urged not expected to buy all—or even most—of your new books from the Club You buy those which it is clearly to your advantage to buy A large proportion of our members, those who live in neighborhoods with well-stocked bookstores, actually buy only the book-of-the-month from the Club, whenever they find it is a book they surely do not want to miss. They continue to "browse in bookstores" for their other books.

Wby BARTLET'I'S FAMILIAR QUOTATIONS is offered to you—FREE

As explained above, BARTLITT'S FAMILIAR QUOIA-TIONS IS one of the Club's latest book-dividends. We offer to give it to new members as a demonstration of how advantageous it is to subscribe to this unique service.

If there is one book—aside from a good dictionary, a Bible, and a Shakespeare—that belongs in every American library, it is surely BARTIFTT'S FAMILIAR

JOHN BARTLETT The Old Cambridge Bookseller

Old John Bertlett's bookstore was a rendezvous for Harvard students and professors back in the eighteen fifties. Whenever they were not sure of the origin of a quotation, they would go to John Bartlett, confident that they could depend upon him for the correct answer. After a time, the old bookseller began jotting down these quotations and their sources in his notebook. This was the genesis of his famous FAMILIAR QUOTATIONS in 1855.

I dition has followed edition, and now comes the Eleventh Ldition, the first in a quarter century. One wonders what old John Bartlett would say today if he could see this monumental volume. Its index alone cover. 117 pages. Not only use the shortsighted omissions of the past corrected (Hawthorne, Melville, Emily Dickinson, William Blake, and many another were curiously omitted). But here is also a welcome gathering of newcomers, where one is sure to find an old friend, whether he is looking for George Adeor for Thomas Mann, for Heisey Allen, T. S. Eliot, or Will Rogers.

QUOTATIONS The new Eleventh Edition offered here (the first revision in a quarter century) is inexhaustable. Its index alone covers 117 pages.

What to Do

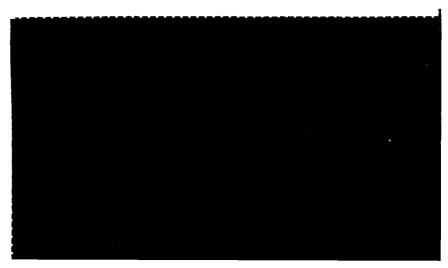

Mail the postcard below, and a copy of this great volume will be put aside in your name. We will then send you a booklet outlining in detail precisely how the Club operates. In particular, it will explain how such enormous values can be given to book buyers

If, after reading the booklet we shall send you, you decide to join the Club, and send in your subscription, we shall at once send you the free copy of BARTLETT'S FAMILIAR QUOTATIONS being held for you

Over 175,000 book-reading families—composed of just such discerning but busy readers as yourself—now use this sensible, thorough and economical means of keeping up with the best new books

MAIL THIS CARD

NO STAMP NEEDED

ALL THESE BOOKS WERE DISTRIBUTED FILE

among members of the Book-of-the-Month Club

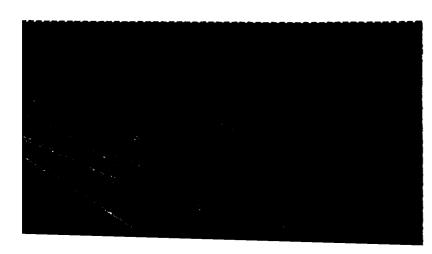

brary volume, free They are called "book-dividends." As a member, you would receive one for every two books-of-the-month you bought. All the books illustrated above were such book-dividends;

BARTLETT'S FAMILIAR QUOTATIONS IS the one being currently distributed.

If you watch best-seller lists, you will observe that the book-of-the-month is always considered, by the reading public itself, among the most popular current books. Frequently it is a book you are extremely anxious not to miss. Whenever this is the case, obviously you benefit enormously by buying it from the Club-because of this unique book-dividend system. Last year over \$2,500,000 worth of books were distributed free-not sold, mind you!among the Club's members.

You Buy What You Please

But, please understand, there is no compulsion upon you, as a member, to take any book-

need a HOBB

Let Leisure League Books Help You Select The Right One

T is no mere accident that so many prominent and successful people have hobbies. FROM WHICH TO CHOOSE

And, while presidents go fishing, bankers paint pictures and famous writers play at farming, thousands of others are finding the power to rise above humdrum jobs through the many new qualities that hobbies are developing in their natures.

A HOBBY CAN HELP YOU IN MANY WAYS

It will not only bring more real fun into your life but will help you to forget your froubles, overcome boredom, make you more entertaining to others and it may even help you to win the respect and admiration of the most influential people in your community.

Hobbies often make friends for you... make you more interesting . . . get you invited places.

A HOBBY CAN BRING PROFITS

Many a man has found, through his hobby, a new source of income when all other avenues have failed. Many a career has been changed by a hobby. Many a sparetime dollar is rolling in to people who started a hobby "just for the fun of it".

LEISURE LEAGUE-A NON-PROFIT ORGANIZATION-WILL HELP YOU!

Selecting a hobby is like getting married—it's usually a life-time choice. So choose your hobby carefully—wisely. Let the Leisure League help you. The Leisure League is a non-profit organization formed with the idea of helping people get more fun out of their spare time. It offers you low cost hobby guide books telling the how and why of many popular pastimes. One of the quickest, best and surest methods of deciding on the hobby that will best suit your needs is to read at least three of these Interesting and informative books. They are listed in the center of this advertisement

ANY THREE HOBBY BOOKS \$ 100 "Care and Feeding of Hobby Horses" Included FREE

This fascinating FREE book is packed full of hobby information. It is written by Earnest Elmo Calkins, one of America's great advertising men—a man who has mastered the art of living both at work and at play. It lists hundreds of hobbies, classifies them, tells you how to get started.

SPECIAL OFFER!

Fill out the coupon today. For only \$1.00 the Leisure League will send you any three of the 35¢ Hobby Guides listed above and include "Care and Feeding of Hobby Horses" free of extra charge.

TWO of the apes, both females, of the colony of pedigreed "apes of science" described in the opening article of this month's number are shown on our front cover. One has a young baby at her breast and each is grooming the other. Momentarily, however, the chimpansee at the right is distracted by the photographer. These and other spes are being bred to be used by psychologists, biologists, and anthropologists because apes are man's nearest animal relatives.

OUR POINT

Astrology

STATEMENT on this page last A month explained why this journal does not conduct the scientific investigation of water witching or dowsing for underground water which is often urged by readers. Its editors are still more frequently urged to investigate and disprove astrology. This question has been

given some thought.

11

As is made clear by the science of logic, any argument between two persons or sides on a given question must be based in final analysis on a premise which both sides accept in common. If there is none, there is no real meeting between the minds of the contestants they never come to actual grips at all The logic that flows on and on may be wholly flawless, yet, being based on dif fering premises, it merely agitates the atoms of the atmosphere. Most of the superheated arguments which we human beings get into (and enjoy, anyway!) are instances of this unobserved error.

Reduced to nakedness it seems to us that the argument about astrology falls in the same category: the scientifically minded and the occult minded cannot agree on premises in common. True, when cornered, the astrologer asserts "You believe in the distant influence of gravitation between planets, don't you' Well, then" This, however, turns out

to be a sort of pseudo-premise

To us it seems unlikely that any kind of direct attack will knock out astrology, in the useful sense that it will succeed in knocking astrology out of the people who follow it. We scientific people might "disprove" it up to the hilt (if necessary) but still our disproof would not have the hoped-for effects. A surer though slower process seems more likely to be the constantly improving standards of general education.-A. G. 1.

Sociological

NOT quite five years ago, the legislative experiment known as Prohibition came to an end. Preceding its demise by almost a year, an editorial in the June, 1932, Scientific American urged that quick action be taken by the government in concurrence with the rapidly growing sentiment of the people in favor of repeal. Our reasons were three-fold. First, we were aghast at the federal deficit of \$903,000,000 that had piled up during the fiscal year 1931 and the prospect of another totalling two billions in 1932; and we predicted a government revenue, to use against these deficits, of a billion dellars a year from legalized

control of liquor. There was also to be saved a large part of the enormous prohibition-enforcement outlay. Second, repeal would promote temperance! Third, the underworld would have, in repeal, amputation of its very great source of income-an income with which it had financed an unprecedented wave of crime and had seduced "the law" itself

What, then, has happened in five years? Just this: all three of our predictions have been fulfilled. From liquor, the government realized revenues totalling a billion dollars in 1937. Temperance has made such headway that, in 1937, the American people drank just over a gallon of spirits per capita compared with two gallons in the normal. pre-war year 1916. Moreover, on this point, statements have recently been made to the effect that less liquor is heing consumed in public and more in the calm atmosphere of the home. As to bootlegging, little need be said. Gone is the rum row that used to lie off each of our coasts, speakeasies have been reduced almost to the vanishing point, and still seizures have come down from 25,000 in 1930 to 11,407 m 1937 Bootlegging has, in fact, been demoted from the ranks of big business, and the few remaining "hig shots" of crime have been forced to fall back into less lucrative, more easily detected rackets.

Sociologically, this experience should have a meaning for all those who think they know what is best for the American people and presume to translate then personal opinions into laws It should show, for one thing, that our people are a pretty level-headed and dependable lot Given personal freedom of action in regard to liquor, they have more than come up to scratch and shown their self control and temperance Give them more chances to express their individuality. where this is now denied them by fiat, and they will without doubt show such evidence of temperate judgment and action as will redound to the benefit of all.—F. D. M.

Canals

FIFTY years ago the Panama Canal was still under construction and seemingly insurmountable obstacles loomed ahead. Regular readers of our feature "Fifty Years Ago In Scientific American" have caught glimpses of the troubles that beset de Lesseps and of the sentiment which, at that time, was growing strongly in favor of a Nicaraguan canal. We cannot here go into the political and financial machinations that made possible the final completion of the Panama Canal, but recent developments have once more opened the whole subject of marine transportation between the Atlantic and Pacific, particularly for our naval vessels and auxiliaries.

Pleas have been made for bombproofing the Panama Canal; agitation has been renewed for a second canal across Nicaragua, partly to relieve pressure on the Panama Canal in time of stress and partly to provide a second avenue for merchant and naval vessels in case of damage to the existing waterway. Such damage, particularly in time of war, would be disastrous since it would force our warships, troop-ships, and those carrying needed supplies and food to travel the extra thousands of miles around the Horn. Bomb-proofing the Canal is a large order, but it is obvious that every precaution must be taken to prevent disaster at any one of the many strategic points along its course.

On the other hand, a second waterway would be of great value in times of peace as well as in the event of war. It would go far to insure that marine traffic would be uninterrupted by any cause and would make doubly difficult the destruction of our invaluable link between the two oceans. The way is open for the construction of a canal across Nicaragua, This country holds a 99-year lease on the right-of-way. Experience in the construction and operation of the Panama Canal has taught many valuable lessons that could be applied in the work on another canal. As shown by a note on the "Fifty Years Ago" page in this number, the surveys of the Nicaraguan canal route had even then been carried out with great care and foresight "in marked contrast with those previously made for the Panama Canal.

With such a background, and with the advantages of Lake Nicaragua as a part of the proposed canal, there should be no untoward difficulties in pressing the work to completion. The way is open. The end is a desirable one. Our merchant vessels and our battle fleets must be assured of a safe passageway between oceans. And the route through the proposed canal would be some thousand miles shorter than the present course through the Panama Canal. The advantages of two canals are obvious. May the powers-that-be see with a clear eye and do their utmost to bring to completion a project that will be of tremendous value to the United States as well as to the commerce of the entire world.-A. P. P.

50 Years Ago in . . .

(Condensed From Issues of February, 1889)

CANAL—"Every discouraging report, for the past year or two, touching the probability of the completion of the Panama Canal, commenced by M de Lesseps, has caused public attention to be yet more earnestly attracted to the Nicaragua Ship Canal project. The great difficulty and the enormous cost of the work thus far done at Panama have compelled those interested in the Nicaragua route to be extremely thorough and careful in their surveys and estimates, which have been completed with a detail that is in marked contrast with those previously made for the Panama Canal."

MACHINE GUN—"The Maxim gun . has met with marked success, and has been adopted by nearly all the European powers, including England, France, Germany, Italy, Switzerland, Austria, and Russia. The gun is soon to be tested at the proving grounds at Annapolis, with a view to procuring its adoption by the United States government. The speed of fire of the rifle caliber gun using the American cartridge is very high, being 700 per minute. The one

pounder will discharge 400 shots per minute. A six pounder adapted to fire shrapnel and grape canister will discharge at the rate of 150 per minute... The Maxim automatic mitrailleuse is so constructed that, on firing a single shot to start the gun, the force of the recoil is utilized for extracting the empty cartridge case and for effecting the various operations necessary in reloading and again firing the arm."

EXHIBITION—"The first impression one receives on a general survey of the Paris exhibition buildings is an exceedingly favorable one. There is a something about them that is pleasantly impressive, and this feeling augments as one passes through the various departments... It is reported... that Edison proposes to span the machinery department with a rainbow of incandescent electric lights, which would, without doubt, he a most effective exhibit."

ALLIGATORS—"The alligator of the South, like the buffalo of the West, is likely soon to become extinct. The slaughter of the alligator for its hide, like the slaughter of buffaloes for their hides, has been so great that it may be only a few years before the lonely lagoon of Florida will have lost its last survivor."

SMALLPOX—"In Paris, where the law requiring vaccination is feebly enforced, the mortality from smallpox ranges from 1.36 to 10 0 to the 100,000 inhabitants, while in the principal German cities, where the vaccination laws are rigidly enforced, the death rate is but 144 to the 100,000 inhabitants, London, under compulsory vaccination, has a death rate from smallpox of but 0.6 to the 100,000 inhabitants."

PIPED WIRES—"The Consolidated Gas Light Co., of this city, some years ago, in laying a gas main, took advantage of the opportunity to introduce a telephone line in it, suspending it from insulators within the main. Excellent results were attained. On recently opening the main the wire was found to be coated with naphthalene, but the line as such was intact."

CIGARS—"There are 1,800 cigar factories in New York City. Of these the great majority employ from one to fifty hands each. Large factories, of which there are 350, employ from 50 to 500 hands, while the largest class of factories, of which there are only ten, employ from 500 to 1,000 hands."

VERSATILE—"A well recently bored for gas at Pitisburgh delivers fresh water, salt water, and gas at same time. There are two casings, one within the other, the outer one, 100 ft. down, taps a fresh water stratum, while the inner pipe reaches the salt water and gas at 200 feet down."

TALL—"The Fiffel Tower in Paris had reached a height of 761 feet on January 9, 1889—the highest structure upon the globe,"

WIRELESS—"When we contrast the present state of electric science... with its condition a year ago, we are struck with the remarkable advances that have been made.... The most important experiments bearing on the theory of electricity have been those of Hertz on the propagation of electrical disturbances... Hertz has obtained electric oscillations of a very short period—several hundred millions in a second—and he has shown that electro-magnet waves caused by them are propagated in the surrounding space, and are reflected and interfere with one another as do waves of light."

REFRIGERATION—"The refrigerator cars in which meat is brought from Western stock yards to Eastern markets are 29 feet long inside, 8 feet 2 inches wide inside, and 7 feet 2 inches from the floor to the cross beams to which the hooks are fastened, above which is a space of 14 inches to the roof. At each end are galvanized iron tanks filled with a mixture of pounded ice and coarse salt. . . . The cars are iced the day before shipping, refilled just before loading, and are iced again every twenty-four hours at regular stations on the route."

CLAY—"Electricity is being more and more used for the purification of kaolin and other porcelain clays. The clay is sifted on to a rapidly revolving horizontal plate, which is surrounded with powerful electro-magnets, which retain the particles of iron.... The process is said to be comparatively cheap and very rapid, and since its introduction many clays hitherto rejected as containing too much iron have become of value for the manufacture of pottery."

PATTERN OF A GOLFER-BY PHOTOGRAPHY

MORE and more industrial problems are being solved by the ultra-speed photography process developed by Dr. Harold Edgerton at Massachusetts Institute of Technology. To the manufacturer of golf balls and clubs, for example, the above photograph from the newly established Research Department of A. G. Spalding & Bros. has an important story to tell. In making it, the camera shutter was opened and, as the golfer started his swing, an intense light started flashing so that each flash caught the club in a different position. Here, each exposure was made at a speed of 1/100,000 of a second. The teed ball, of course, was registered on the film with every flash during the downward stroke. The golfer did hit it—and the hall flies off to the right. Note the upward flight of the tee, as well as the angle of the club face and the fact that the golfer lifted his head!

The Laboratory Building of Yale Laboratories of Primate Biology, Orange Park, Florida. Here in cleanly cages chimpansees are being bred for the uses of science, as experiments made on the apes may be of greater value to biologists, anthropologists, and psychologists than those in which dogs, rats, guineapigs, monkeys, and other animals more distantly related to human beings are employed

Dated Chimpanzees

PLORIDA boasts the world's strangest colony—dated chimpanzees. In the salubrious atmosphere of subtropical Orange Park, there jabber, leap, climb, shriek, mutter, and multiply dozens of pedigreed anthropoid apes.

And, incredibly enough, in this flourishing colony, these startlingly man-like creatures are to be bred—or rather, manufactured—to specification. A standardized, all-purpose ape is the ideal laid down in the blueprints. Nowhere else in creation is there such a laboratory.

If, some fine day, you should drive through the balmy and luxuriant northern Florida countryside, and at last reach the low and spreading buildings of this great laboratory—for great laboratory it is, and not a zoo—you would readily single out cage after cage of squat, dark, hairy figures—babies, youngsters, and adults—loafing in the shade or waddling clumsily about in the sunshine. Coming closer, you could not help noting how bright-eyed, healthy, and clean is this animal colony. And you would observe no scratching of fleas. Indeed, each cage is well-kept.

Perhaps with astonishment, as you watched the attendants going about with food, apparatus, and notebooks, you would absorb the significant fact that human beings rarely get more careful consideration or more individual attention. Indeed, the colony was founded because these apes are among the most manlike of all creatures—and because an eminent scientist had the fortunate idea that the more like human beings these animals are treated, the

more the discoveries directly applicable to human problems.

Yale's Ape Colony, in Florida, is a Laboratory in Which Discoveries Directly Applicable to Man are Being Made on Man's Closest Relative, the Ape

The chimpanzee who showed where his gums ached. Moos in his fifth year

"A single chimpanzee wisely used may be worth more than thousands of guineapigs," says the moving force and guiding genius behind this unique undertaking, Robert M. Yerkes, a distinguished professor of biology at Yale University. "The primary intent of the administration is to produce chimpanzee subjects which by type, breeding, rearing, and general adaptation shall be pre-eminently suitable for research purposes in lieu of human subjects." The laboratories are under the auspices of Yale University and have been supported financially by the Rockefeller Foundation.

There are countless human problems of utmost importance which are vitally in need of solution but upon which research simply cannot be carried out with human subjects. Such experimentation must deal with dire diseases, including syphilis, and with the brain and problems of behavior, as well as with the more intimate aspects of glands, sex, and reproduction. The ape must come to the rescue of man.

How strikingly human the chimpanzee at heart—especially after his confidence in investigators and their good will has been brought to a high point over a period of years—has astounded even Dr. Yerkes. He relates an actual incident to drive the fact home.

Moos, a young male, had been ill, and was convalescing. But he was evidently still in pain and would refuse all solid food. Moos had already been given repeated close examinations. His attendant, however, determined to find the source

of his pain. Refusing solid food suggested a toothache. The investigator went into the cage to

By BARCLAY MOON NEWMAN

look Moos over once more. The young chimpanzee greeted him cordially, and calmly, even hopefully, submitted to the new examination. Yet the investigator could see no evidence of dental difficulty. Shrugging, he turned away to open the door and leave. Moos thereupon reached over and plucked the attendant's coat, drawing him back. Then he poked up his upper lip with a finger of one hand, and with a finger of the other hand pointed to a spot on his upper gum. Peering in-

The twins—only chimpanzee twins known—enjoying a playing spell

tently, the attendant was at last able to discern a swelling. A new tooth was about to break through And Moos thus solved his own difficulty.

Perhaps still more remarkable, the chimpanzees soon learn that no harm is meant them even during uncomfortable experimenting and, like Moos, will eagerly try to help the investigation along. When Fifi has several times been made to sit down at a table and has been afterward trussed up with complicated apparatus, from which stimuli may mysteriously come, one day she rises to the occasion in true ladvlike fashion Upon being introduced into the experimental chamber, she walks to the table, seats herself in the little chair, placidly folds her arms and waits for the investigators to truss her up and perhaps shock her with electric currents

Also, with almost human intelligence, they learn to obey spoken commands, gestures, and gentle shoves. Often it is feasible merely to go through the motions of what is expected of the ape, and he or she will react by imitation of the investigators' actions. Of course, when Fifi, Moos, and Mimi do their chores admirably, they are rewarded suitably with a banana or an orange. Next time, their confidence increasing, they are successfully encouraged to do more difficult tasks.

In fact, affection, and ludicrously even deep sentiment, may spring up in the maturing chimpanzee's heart and the eager creature will attempt to outdo himself. Further, sentiment may go so far as to prove decidedly embarrassing—hugging and kissing and little love-taps are demonstrations of the surging emotion within. On the scientists' part, the chimpanzee youngsters are treated like so many children.

Under this regime of extraordinary care and sympathy, and of research into the manifold difficulties and unknowns incident to undertaking the production of apes, the colony has indeed flourished. At the start, in 1925, there were only two chimpanzees, of opposite sex. To day, the population is approaching three score.

So, for more than a decade, increasing numbers of chimpanzees have been maintained alive and healthy in captivity. Their handling and rearing have been so successful that they have multiplied rapidly. This demonstrates how scientifically and painstakingly the enterprise has been developed

THE chimpanzees are subjected to a rigid routine—so that they have enough exercise, a diet making for health, and sufficient repose Their diet has been given intensive study—perhaps more study than any other factor. Not only are the calories measured, but each essential nutrient—carbohydrate, fat, protein, mineral, and vitamin—is provided. Few groups of human beings are better nourished.

Strict hygienic measures are unbreakable law Well-groomed are these apes, and quite free from vermin Mental hygiene, too, is not neglected. No chimpanzee is ever teased or otherwise unnecessarily annoyed Over-excitement of these charges is avoided. And throughout its entire life, every creature is kindly treated

At present, and for a long time to come, practically all these thoughtful procedures on the part of the apes' supervisors are directed toward the eventual mass production of a standardized chimpanzee. The ideal called for in the blueprints has its features as carefully detailed as those in any set of plans for a new model car. The records of every series of experiments carried out with the aid of any given ape are analyzed laboriously in the light of this ideal.

"The ideal chimpanzee must be small and tobust," states Dr. Yerkes, who then adds a multitude of other characteristics to be established by careful breeding and selection. The ape must be disease resistant—"preferably with varied specific immunities" to diseases. Reproduction must be rapid. And he must not take too long to grow up and reach maturity.

Intelligence is important Furthermore, Mr. and Miss Chimpanzee must understand how to behave himself or herself though shifted from one environment to another. He and she must be active, yet not destructive; co-operative, emotionally stable, dependable, and kindly disposed towards the world in general. On the whole, the ideal ape is easy to handle, being ever calm but capable of warm friendship.

Finally, the ideal race not only is to breed true to type (or standard) generation after generation, but also is to be a producer of twins.

Why twins? In twins are hidden untold treasures for the searchers after the secrets of heredity and of the environment's influence in modifying heredity. In human twins, the vast and almost immeasurable hereditary differences between human beings are reduced to a minimum. The study of a pair of twins, particularly if reared in different environments, tells scientists a great deal about what traits and talents are fixed by heredity and what influence a poor or a good home or education or group of contacts may have upon inborn character. Such studies have already transformed the science of criminology as well as many another important social investigation. So, chimpanzees being remarkably similar to men, chimpanzee twins can be expected to carry on the profitable work

Thus far, only one pair of twins has blessed the colony. But this pair marks

Chimpanzee family, mother holding the baby as in playful display

an important beginning. The capacity for producing twins may run in families. Hence these twins, properly mated later with other twins, may give rise to apes given to twinning.

Along other lines, significant discoveries applicable to man have already been made by using chimpanzees. The staff of investigators has contributed many new facts concerning the processes of learning, the development of intelligence with increasing age, and the power to adapt oneself to changing environments. In most respects human behavior

is not by any means fundamentally different from behavior in higher animals. Moreover, observing animals always gives excellent leads towards the secrets of basic human emotions, attitudes towards new companions and new situations, and personality as a whole.

Observing a steady stream of near-tohuman-type births in monkeys and apes is today providing the medical specialists with knowledge concerning birth problems. That such discoveries are being made and are of vital meaning to man is not surprising. Never before have medical experts been able to approach so close to certain features of childbearing or been able to experiment so searchingly in this field.

A great list of experiments has already been drawn up in this early stage of the program. The invaluable investigations should proceed, ever more fruitfully, as the colony continues to increase After a decade, the success of the colony and of the plans for it have been proved. A major scientific and medical feat is being achieved.

Like all pioneers, Dr. Yerkes has been first a dreamer, and then has found in his dreams inspiration for action.

TWO decades ago, while musing upon the search after the secrets of life, and especially human life, he spotted a failure on the part of his fellow scientists. Everywhere biologists, psychologists, and medical investigators were studying the structure, vital chemistry, and diseases of animals—guinea-pigs, iats, monkeys, sometimes (rarely) chimpanzees. With what wonderful precision these investigators were working! How accurate all the vast and delicate modern laboratory equipment! How marvelously keen and sensitive these innumerable gleaming 'scopes!

But just here a startling thought flashed into his mind. Precision instruments were, throughout the scientific world, being used on biological specimens—primarily so that the resultant discoveries could be applied to man. Yet upon what sort of specimens were all these painstaking observations being made? Here was the surprising neglect.

The alley cat, the stray dog, a monkey kidnapped in the jungle, pondered Dr. Yerkes, are the utterly unknown specimens upon which precision measurements are being wasted. Who knows the history of such specimens picked up haphazard-often diseased, of unknown age as a rule, probably often abnormal in ways disastrous to true scientific precision? And as for any of the forms most closely related to man, they are obtainable only with the greatest difficultyand when obtainable are decidedly the most haphazard of all specimens. All available apes were simply snatched from the jungle or bought from natives.

Strikingly poor specimens make all

Mona, the mother, and her boy and girl twins, photographed when one year old

findings strikingly poor—the highest scientific care comes to nought where thousand-dollar instruments are turned upon ten-cent specimens. And often it is a far cry from the guinea-pig or the albino rat, or even the monkey, to the high estate of man.

"Truly," asserts Dr. Yerkes, "extraordinary risks have been taken." After new drugs are found beneficial in animal maladies, they are tried out on human beings. But who knows to what sort of animal this new drug is really valuable? It may be to an abnormal animal—the exception—or only to some lower creature at most distantly related to man,

Now Dr Yerkes was, and is, more than a mere biologist. His speciality is that remarkable field, psychobiology, whose grand attempt it is to explore the influence of bodily processes upon mental characteristics and behavior and, at last, problems of society. And in this work, which is so closely bound up with human interests and the entire science of man, he had come to study the ape as a form more like man than any other living thing. The chimpanzee had been his choice-really had to be the anthropoid for his experiments. Gorillas are almost unobtainable. Orang-outans are sluggish and solitary. Besides, the chimpanzee is the ape most tractable, most adaptable to conditions of captivity, the least expensive (though still costly), and is by far the best understood scientificallyas to anatomy, living processes, nutritional needs, reproductive peculiarities, and general personality.

And so, not denying the possible future use and possible peculiar advantages of the gorilla and orang-outan-advantages still to be discovered—Dr. Yerkes looked to the chimpanzee. And

the chimpanzee, we see, has not failed him.

Years were spent in planning the program, including methods of keeping the animals alive and healthy, and means of bringing about successful multiplication. The blueprints of the ideal were finally worked out. To these specifications the chimpanzees were eventually to be molded through wise breeding procedures. Northern Florida offered the most favorble climate.

IN 1925, a young mate and a young fe-male were bought from a dealer, who had brought them in from Africa. Of course, these creatures—the Adam and Eve of the Florida Eden-being taken in the jungle, had no pedigrees. Still, a start had to be made somewhere. At any rate, Adam and Eve turned out to be fairly satisfactory and quite healthy. Later, several additional apes were purchased. But meanwhile, natural reproduction under the favorable colony conditions commenced. Infants began to appear, not merely healthy but happy and friendly as they developed into chimpanzee children, from birth accustomed to friendly man. Now there have been more than a score of perfect births-including the birth of the twins who may give rise to a dynasty of twinning apes.

The standard, all-purpose chimpanzee, peculiarly fitted for scientific experimentation and perhaps for later (though still uncertain) routine tests in hospitals—to save the lives of countless men—is on the way.

"The aim," Dr. Yerkes tells us, "is to create a breeding colony which shall have only dated individuals of known history and condition."

A FASTER ARMY RIFLE

NOR many years the Ordnance Department of the United States Army has devoted an intensive effort toward the development of a satisfactory semi-automatic, or self-loading, rifle Such a rifle would omit the side bolt of the present Springfield and permit the individual soldier to fire an entire clip of cartridges without once removing the butt from his shoulder. A distinct advantage foreseen would reside in the soldier's ability to hold his rifle on his target without the necessity, as with the Springfield, of dropping the gun to the port position to slide the bolt by hand. It would be necessary for him only to

pull the trigger for each shot Some years after the World War, the search for such a weapon narrowed down to a caliber .276 rifle. Before a final decision was reached on this weapon, a caliber .30 semi-automatic rifle was completed after many years of work by John C. Garand, a designer in the employ of the Ordnance Department at the

Springfield Armory. The results of tests on this weapon were so excellent that the caliber 276 was abandoned and the Garand semi-automatic rifle adopted as the standard weapon for the United

> The new Garand rifle, at left, is without the side bolt. However, it does have a small operating lever for the mitial"cocking," as shown in photograph, at right, of open breech and clip of eight cartridges

Garand Semi-Automatic Rifle Adopted by U. S. Army . . . Self-Loading . . . Fires Clip of Eight Cartridges . . . More Rapid Fire, Gun Held on Target

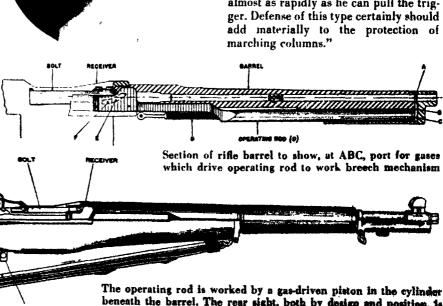

States Army. During the next few years, our entire Army will be equipped with this weapon.

The new M1 rifle is described in Army Ordnance by Frank J. Jervey as "a gasoperated, clip-fed, self-loading, shoulder weapon slightly over nine pounds in weight. It fires the same ammunition as the caliber .30, M1903 (Springfield) rifle and all standard U.S. caliber .30 machine guns. The ammunition is supplied in eight-round, reversible, en bloc clips which are fed by hand into the magazine of the rifle. Upon being inserted, the clip depresses the follower which in turn releases a catch, allowing the bolt to go forward under the action of a compressed spring, stripping the top cartridge from the clip and chambering it When the last round in the clip is

fired and the empty case is ejected, the clip also is ejected and the bolt is retained in the open position ready for the insertion of the next loaded clip.

"It generally is conceded that for short periods of fire the M1 has the value of approximately three bolt-action rifles. . . . The lack of fatigue after continuous firing and the ease with which the rifle can be held on the target throughout the firing of a complete clip is remarkable for the type of fire. . . . The average rifleman is capable of firing about 40 shots per minute." One case tells of 80 shots at 200 yards in one minute, all hits within the target's "4" ring.

"The rifle shows its greatest superior ity over the Springfield in anti-aircraft work. . . . In the M1 (the Garand), the 'kick' is very light, and it is easy to keep the rifle on the target throughout succeeding shots. The advantage of this for defense against high-speed, low-altitude aircraft where the target is present for a fractional period of time can be readily appreciated. Try, for a moment, to visualize a company of soldiers on the march, equipped with semi-automatic rifles, An airplane traveling at a speed of about 200 miles an hour suddenly appears over the top of the trees. Within a split second, each man can bring his rifle to his shoulder and begin firing eight rounds almost as rapidly as he can pull the trigger. Defense of this type certainly should

beneath the barrel. The rear sight, both by design and position, is said to be the finest, most efficient, on any military rifle in the world

Bubbles

A Fascinating Little Experiment Reveals a Surprise and Later May Lead to Some Utilitarian Purpose

WHAT shape is a common hubble of air rising through water? Some night answer offhand: "Round." Others with better memory of casual observations might put it: "Spherical, in general, but constantly wobbling." The ultra-slow motion picture series at the right shows what really happenshapes and antics previously unrealized.

In the top picture a balloon-shaped bubble of air surrounded by water is just leaving an adjustable orifice at the bottom of a vessel 3 inches in depth,

About 1/100 second later it is breaking off and starting to rise—second picture.

In the third picture, approximately 1/1000 second later, the bubble is on its way upward. The clongation at its bottom has contracted and been pulled upward into the bubble. Note the truncation of the bottom thus produced, also the tip of the pulled-in part dimly showing within the bubble.

In the fourth picture, taken about 1/300 second later, the bottom is pulled farther in and the little tip inside has cast off a tiny water droplet.

In the fifth this little drop is rapidly moving toward the top of the bubble.

In the sixth it is about to strike the top.

About 1/600 second later, in the seventh, it has struck the bubble's ceiling, made a neat little "goose-egg" on its head and rebounded downward.

And now see what happens! That little blow from the droplet has set up waves that travel all over the bubble and give it, 1/100 second after the previous picture, the strange shape shown in the eighth picture.

The final picture, taken about 1/400 (.00024) second later, shows the amazing shape a bubble can assume!

To researches such as this there are several well-known types of reaction. The person of limited imagination, who calls himself "practical," scornfully says: "So what?"—and walks away, pitying the poor experimenter. On the other hand, the scientist, all boy, probably remarks that these observations provide a fascinating illustration of Somebody's-law, and that the industrial people probably could find some application of them to industry—leave it to them. The broad-gage industrial man is boy plus scientist plus truly practical, so he says: "Let's play with these bubbles some more, and see if we can find something applicable in them—you never can tell."

The application hasn't yet been hit on, but "the practical applications of the bubbling of gases through liquids are almost universal, and we have no doubt that there will be such," stated Dr. Gustavus J. Esselen, of Boston, Massachusetts, in describing this research before the American Chemical Society. "The processes of flotation of ores, the formation of lather and suds with detergents, the washing of gases both for absorption and for cleaning, the formation of gases we can also have expectation of liquids into

Line Aller

gases as in carburetion, and numerous other applications of contact between gases and liquids can easily be cataloged," according to Dr. Esselen. "Which of these will be affected and to what extent can at the present moment be only guessed.

"What has been learned so far is that the bubbling of air through water is far more complex than one would anticipate. Instead of rising through the liquid in the spherical or nearly spherical form resulting from the action of surface tension forces, air bubbles assume a variety of forms apparently through the operation of forces hitherto unsuspected.

"A separate set of forces is set in operation by the formation within the air bubble of a tiny globule of liquid water which, given momentum by the force of surface tension which breaks it away from the inner surface of the bubble, bounces up and down within it. These globules of water do not merge with the bubble walls, but possessing high speed, and hence substantial momentum, they bounce off the inner surfaces of the bubbles as if the surface film lining the bubbles were made of rubber and the globules were tiny balls.

"The effects of these collisions between bubble wall and water globule are evident in wave motions imparted to the bubble, which continuously changes its shape as it rises through the liquid. These can be readily seen in motion pictures and in prints of parts taken from them.

"STRIKING, too, is the difference in behavior evident when a wetting agent is added to the water in which the bubbles are formed. The basic effect of the wetting agent is to reduce the surface tension of the water and thus the strength of the film surrounding the bubble. For this reason, the bubbles show a pronounced tendency to merge together and the bouncing of the globule of water can no longer occur because at the first contact with the weakened surface film it is able to penetrate into the surrounding liquid.

"Quite obviously, the behavior of bubbles in liquids depends upon the character of the liquid and more particularly on the strength of the surface film which it forms around the gas bubble.

"Throughout our experiments the temperature of the water was maintained at 20 degrees, Centigrade (68 degrees, Fahrenheit). The size of the orifice varied from 0.53 millimeters to 7.5 millimeters, covering a ratio of area of 1:200. Four different air velocities were used-50 cubic centimeters, 150 cubic centimeters, 600 cubic centimeters, and 1200 cubic centimeters per minute. With an air flow of 150 centimeters per minute the tendency for these globules to form decreases as the orifice size increases from 0.53 millimeters to three millimeters diameter. With the three millimeters orifice, no globules are observed with an air flow of 150 cubic centimeters per minute. As the orifice diameter is further increased the globules are again formed. These results are presented in the following table:

Globule Formation Inside Air Bubbles

Air Flow ce per minuta 150	Diameter of Orlfice millimeters 0.53	Globula Pormation percent 50
150	2	20
150	3	0
150 .	4 9	80
150	7.5	100

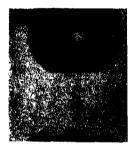

"The figures presented in the column headed 'Globule Formation' were obtained by counting the number of air bubbles in which the formation of globules was observed and calculating from the total number."

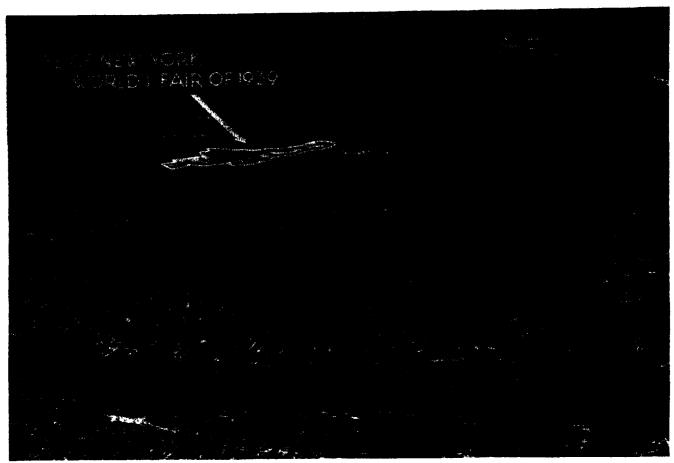

The Fair is directly northeast from the midtown business section of Manhattan in the foreground

Up From the Ashes

TEOGRAPHICALLY, New York when the tremendous advantage of possessing one of the world's finest harbors and a very lengthy landlocked shore-front for waterfront and shipping developments. There are, however, some physical disadvantages in this since, of the five boroughs of the city, four are on islands separated by arms of the sea. The development of the city has, therefore, been largely a question of bridges and tunnels, either for rapid transit or vehicular traffic. Curious backwaters have developed in various portions of the metropolitan area due to absence of these facilities or failure to exploit them

Near the geographical center of the city, which is also very close to the center of population, there developed in the Borough of Queens one of these backwaters, bounded roughly by Queens Boulevard—which is opposite 59th Street, Manhattan—Flushing River, Flushing Bay, and the East River, and covering an area of about 16 square miles Because of marshes and deep indentations, the area could not support, financially, the necessary reclamation or improvements, grading, and proper paving.

New York World's Fair 1939 a Glittering Cinderella . . . Engineering Difficulties of Filling in and Building Upon Ash-Filled Swamp Muck

By JOHN P. HOGAN
Chief Engineer and Director of Construction

Many years ago the then city of Brooklyn, needing a place to dispose of its ashes, selected the largest one of these marshes for the purpose at a point where it was about one and one-half miles wide. For a number of years, not only the ashes, but also all the non-perishable debris of an average population of from one to two million people were deposited here. As the ashes were deposited, they sank into the mud to a maximum depth of 40 feet and piled up to a height of nearly 90 feet. Infested with rats, they added to the unattractiveness of the already dreary landscape.

Straddling one of the main entrances to New York, this ugly area formed a blot of the first magnitude. The dumping of ashes was stopped several years ago after about 50,000,000 yards had been placed, but the task of reclamation was thought to be too expensive and too stupendous to be immediately undertaken.

About 1932 things began to happen. The old Triborough Bridge Project was revived. This bridge now connects the three Boroughs of Queens, Bronx, and Manhattan, entering the latter at 125th Street, crossing the East River at Hellgate, and entering Queens at the village of Astoria.

About two years before the opening of the Triborough Bridge, a group of enterprising businessmen of New York decided to hold a World's Fair in New York in 1939 to commemorate the 150th anniversary of the inauguration of George Washington in New York City. In searching for a site that was both

readily accessible to the heart of the city and large enough for the purpose, they found that the desolate marsh fulfilled these requirements better than any other available site. The city plan had always included the rehabilitation of the marsh and dumps to form a grand city park 50 percent larger than Central Park.

Under the stimulus of providing a site for the World's Fair, the city agreed to advance all the necessary items in the general plan for immediate construction and to add thereto the cost of dredging two lakes and leveling the ash dumps over the remaining marsh in order to provide a foundation for the park. The city agreed also to build a permanent park headquarters for use as an exhibit building for the City of New York duiing the Fair and to use its best efforts to get the state to build as its exhibit a permanent amphitheater seating 12,000 people which could also be utilized duiing the Fair

THE Fair Corporation agreed to build four permanent bridges. It agreed further to landscape the site in such a way that the planting done would be useful for later park development, to build several permanent park roads and to leave for the initial stages of the park development all the temporary roads all bridges across Flushing River, and any other structures built by the Fair Corporation which the city would require. A lease, embodying these terms, was signed on June 29, 1936

No time was lost. Prior to the determination of the details of the formal agreement, the contract was awarded for leveling the site on June 15, 1936. Although this required dredging of nearly a million yards of material, and transportation of nearly seven million vards of ashes, the work was completed in eight months, or in April, 1937, two years before the date of the opening of the Fair. The vast tributary works, the road and bridge building, sewer con

struction, and so forth, were put into work as rapidly as detailed plans could be prepared.

The work done by the Fair Corporation itself is only a fraction of the building program for the exposition. The Fair itself has constructed 20 exhibit buildings, a theater, three large railway stations, and a group of administration and operating buildings. In conjunction with the states, it has constructed 13 buildings to house the exhibits of 37 states; in conjunction with the Federal Government, it has constructed eight buildings to house the official exhibits of foreign nations. The building program of participants is much more impressive. Twenty-three of the 62 foreign nations and 43 industrial corporations will erect their own exhibit buildings, and over 50 buildings and amusement devices will be erected in the Amusement Area. It is expected that the total expenditures on account of the Fair will be in the neighborhood of \$150,000,000.

In addition to the exhibit buildings, the Fair Corporation has constructed and will operate utilities, roads, general landscaping—including the planting of 10,000 large trees from 12 to 20 inches in diameter—five permanent bridges and 11 temporary bridges, several large parking fields, and the Theme Center, including the well known Trylon and Perisphere Over \$10,000,000 of the money spent by the

Early work on the site, showing one of the huge ash dumps with its variety of large-city refuse Fair Corporation is underground. Some of the items which helped to make this total are 51 miles of roads and paths; 34 miles of storm drains, sewers, and water mains; 90 miles of electric conduits; and over 500 miles of piling including piles driven by private exhibitors. In this work, and in the development of the foundations, the majority of the engineering problems have been encountered and solved.

The original filling and first stabilization was a delicate operation. The ash dump covered roughly 300 acres of the 1200 acre site. Elsewhere, the site was composed of a peat covering about three feet thick overlying from eight to ten feet of very fine silt with a very high water content Rock was about 400 feet deep below the surface, and therefore out of economic range for foundations Underneath the liquid mud, however, was a bed of very fine sand covering the entire area and formed like a trough with the axis of principal depth three and one-half miles long approximately in the middle of the site. This sand has a supporting capacity of about two tons to the foot, which indicated that it

would support piles loaded with about 18 tons. On most portions of the site where large amounts of ashes had been dumped, the natural surface would support a concentration of about 1500 pounds to the square foot. It was therefore evident that the direct weight of the buildings could be supported on the site.

The main danger, however, was that of lateral movement either during the filling operation or during the construction of the foundations. The original disposal of the ashes had forced them down into the mud, in many cases to a depth of 40 feet. This had been partly compensated for by driving water out of the underlying mud, and partly by the rise of a series of mud waves around

the edge of the dump. In these mud waves, the original peat covering had been forced up in many cases as much as 20 feet above the surface of the swamp and in some cases the underlying mud had flowed through the peat covering. Elsewhere, the peat cover formed a mat upon which to place the ashes excavated from the dump, but it was necessary to place the ashes in three-foot layers and to allow no slopes of more than three feet in 100 to develop, otherwise further flow and additional mud waves might have been created. The bed of the old channel which meandered through the site had to be filled, and this furnished one of the principal problems since it was 15 to 16 feet deep and had no peat cover.

The problem of equilibrium was successfully met. Within certain areas, subsequent settlement continued locally for over one and a half years after the completion of the first filling in April, 1937. The only way in which this local settlement could be met was by a continuance of filling operations. Finally, in the summer of 1938, the last of these local settlements ceased, and today the site is perfectly stable. The process of consolidation was greatly accelerated by the early construction of a large number of storm drains.

In the lower ground along the banks of the new river and the new lakes, it was in many cases necessary to put the sewerage drains and conduits on piles,

and where soft spots developed in the new foundations for roads in this area they were corduroyed with three-inch wooden planks recovered from pile butts. Of the total length of 37 miles of road it was necessary to treat only a mile and a half in this manner. One of the aids in stabilization, where the ash cover was thin, was the action of the piles themselves. The underlying silt is so liquid that it is not compressible. Therefore each pile represented the displacement of an equivalent amount of water from the mud. To meet any lateral movement, most of the pile foundations were connected with reinforced concrete struts.

FLEXIBLE type of pavement was A chosen, both because it would be easier to repair after local settlements, or after excessive wear, and because it was the cheapest type which would give good service. The bus routes and main highways consist of a four-inch thickness of cru-hed stone on which was laid a three-inch layer of cold laid plant-mix bituminous macadam. This is in two courses consisting of a two-inch binder and a one-inch wearing surface. For lighter traffic, a similar plant-mix bituminous macadam is laid directly on the ash fill after proper consolidation. This pavement consists of 2½ inches of binder and a one-inch wearing surface. In courts and gardens, the walks consist of a thinner bituminous mixture laid on a base of cinders.

The most serious foundation problems were encountered at the site of the Trylon and Perisphere, particularly as the Trylon has a maximum wind load equal to about four times its weight. The foundation problem was solved by driving about 1100 creosoted piles from 90 to 95 feet into the underlying sand. These piles were then covered with heavy reinforced concrete and, in the case of the Trylon, these had to be heavy enough to resist the over-turning effect of the wind load. As the Perisphere rests on eight columns, a pile and reinforced concrete foundation was adopted, the whole load of approximately 2500 tons being transmitted through a circular ring girder into the pile foundations.

The Fair itself now promises to be not only the largest of the world's expositions, but one of the most beautiful. Important, too, are the destruction of an eyesore and the promise of a future park, which have started the construction of thousands of apartment houses and dwellings in the neighborhood and thousands more are projected. It has been estimated that a million people will move into the neighborhood within the next ten years.

When Grover A. Whalen, President of the New York World's Fair 1939 Incorporated, opens the Fair to the nations of the world on April 30, 1939, he will have followed to completion a modern miracle—the rise of the New York World's Fair from the ashes!

Even in its far-from-complete condition in October, 1938, the Fair presented a spectacular contrast to the original site.

Test Your Soil

Home Gardener or Commercial Grower May Test Soil With Simple Kits, Grow Better Plants

GARDEN plot or grain field is a tiny chemical laboratory, is made up of countless soil particles, contains complex and intricate chemical processes, and is never the same from week to week, changing as the crop draws on the plant food resources, modified by weather and seasons. The fertility of the garden or farm is directly dependent on what goes on in that earth zone where feeder roots draw sustenance from the earth.

In the past, soil testing to guide the grower has been largely confined to extensive laboratory processes and out of reach of the average grower. Now, however, there is available a simple field kit with which anyone can make tests of soil and determine from them the fertility of any given plot of ground.

As little as two dollars will secure a field kit of the simplest type. Anyone who can read newspaper English and distinguish colors may, in a matter of minutes, run the four principal tests on a soil sample.

The first and most important determination is whether a soil is neutral, acid or alkaline. Some crops, such as asparagus, alfalfa and heliotrope require a soil definitely alkaline. To put such plants in acid soil is inviting failure. Other plants, such as rhododendrons, cranberries, parsnips, and gardenias will be retarded or destroyed by alkalinity. Every soil test kit contains a pamphlet listing the alkali-acid preferences of plants and the degree of either condition they demand. There are instructions as to how to change a soil from acid to alkali, or the reverse.

The other three primary tests are for

plants. The objective of a soil test is to make certain they are present in sufficient quantity and in the balance required by the crop being produced. Nitrogen is the element chiefly re-

quired in leaf and stem growth. Such crops as cabbage and lettuce and bluegrass lawns draw heavily on the nitrogen in the soil. Phosphorus content of soil is linked with the production of flowers and fruits. Any crop of orchard, flower garden, or grain fields needs adequate phosphorus to "make the crop." Potassium stimulates root growth; such a crop as the lowly potato demands this element in the correct balance in the

nitrogen, phosphorus, and potassium.

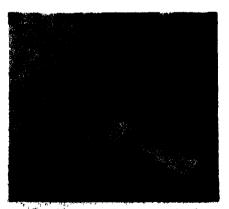

These are the soil chemicals which are

required in large quantity by growing

Each year gardeners and farmers spend millions for "complete" fertilizers that contain a set ratio of the three principal plant foods-nitrogen, phosphorus, and potassium. This gunshot application

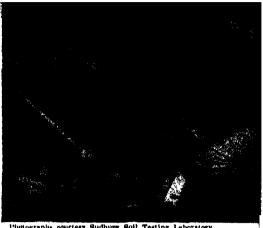

Larger soil testing kits can be used by non-technical market growers

All thicking operations are as simple as pouring a test solution into a tube

The solutions are filtered in the larger sets, in order to clarify colors

Photographs equities Sudbury Soil Testing Laboratory The small soil testing kit, with complete instru tions for using, is about the size of a small bo

of plant foods may not have enough of one or too much of another chemical to supply the needs of the particular crop. The soil test shows what is present and what is lacking, and the grower may buy only those chemicals needed to make his soil highly productive. The possible economy is obvious, for the grower may now be paying out money needlessly for chemicals that are already present in his soil.

HE technique is simple. With an ordi-I nary spoon, dig two inches under the soil surface and scoop up a soil sample. It should be dry enough not to wad up under pressure. Each tube in the kit has a colored cork; each color is for an individual test and each test is made every time in the tube assigned to it. The test tube is filled one fourth full of soil. The kit contains small bottles of test solutions. Selecting the one designated for the test being made, fill the test tube until it is half full. Cork it, shake it, and set it aside until earth particles settle. The liquid above the soil will take on a color. This color is the key to the test.

There are four color charts in each test kit, one for each test. Match the color of the liquid in the tube with a color shade on the chart for the test being made. The shade or tint on the chart will be designated by a key letter or number. Turning to the pamphlet, one finds the answers all worked out. From the resulting data, one can make up his own fertilizer, "tailor-made," for his particular -Arthur Hawthorne Carhart,

Colors in the solutions are matched against those in key color charts

Powder Metallurgy

A NEW process for the manufacture of metal objects is now available to industry. It permits the alloying of metals without the customary melting and casting, while entirely new compositions can be produced from such unrelated materials as metals and abrasitives.

This process is called powder metallurgy, and although it has been known and used for more than a quarter century, it is only now coming into its own as a tool of production. In a manner which seems as simple as filling a doctor's prescription (but isn't) it provides your automobile with oil-less bearings, clutch facings, and spark plug inserts. It offers your home and your family radio tube parts, lamp filaments, dental alloys, warming-pad mixtures, and permanent waves, while to science and industry it contributes X-ray targets, welding electrodes, grinding wheels, and other essential products.

The art, which is characterized by the compression of metals in the non-fluid state, seems now to be on the eve of further commercial expansion. Developments begin to issue in a steady flow; promotion and research run neck and neck to get results now and to promise more in the future, yet there remains a vast unexplored domain which makes definitive evaluations premature.

The exact date of powder metallurgy inception cannot be set. If we say that it began as a science around the turn of the century, the statement can be defended. At that time came the production of tungsten filaments from the metal powder, involving all the applications of technique—preparation of the powder, compression, heat treating, and subsequent processing to form—whereas the production of bronze powders which

antedated filaments by a half-century required only the first of the several producing steps

The manufacture of tungsten filaments called for the metal in a pure state, in bar form, ready for drawing into fine wire, and since tungsten has a melting point of 6100 degrees. Fahrenheit, there was the problem of getting high enough temperatures to reduce the metal to a fluid state as well as the problem of obtaining refractories that would stand such heat. If, however, tungsten oxides are reduced by hydrogen to leave tungsten in a pure powdered state, then the powder can be compressed into bars, sintered or heat-treated, hot-swaged, and drawn.

The process sounds extremely simple, but at the outset it was highly complex.

It was necessary to find a way of eliminating impulties and discover means to control not only the structure of the metal particles but their size and assortment of sizes as well. Then there had to be research to find binders which would be eliminated upon hear treatment; and long study went into determination of the proper pressures to obtain desired densities.

Upon the knowledge acquired by metallurgists in their quest for the best means for producing tungsten filaments, and subsequently molybdenum wire (another high melting point metal), has been reared the new science of powder metallurgy. Today there is hardly a metal known and used by man which is not available in powder form, and used either as a single element or in combination with others.

Developing satisfactory methods for powdering and refining metals to approach some measure of standardization has been a long process and an essential step in the new metallurgy. Out of these labors have come eleven basic processes. These have beer listed in the following manner: machining; milling (by ball mills, stamps, attrition mills, and so on); shotting (pouring molten metal in water, air), granulation (by stirring molten metal while solidifying); atomizing (disintegrating by steam, compressed an); condensation of metal vapor; reduction of oxide powders; chemical precipitation; electrolytic deposition; sintering (for the production of alloy powders in friable form); formation of an alloy followed by dissolving or otherwise remov

Tungsten oxide, placed in long retorts in trays (at left), is heated in an atmosphere of hydrogen until reduced to metallic powder. The powdered metal is then placed in a steel form and pressed into a bar under 14 tons pressure per square inch (right)

ing one of the alloying constituents. The relative importance of these processes cannot be set unless you measure arbitrarily. Importance in volume is one thing; the value of the item produced is another. It is enough to say that the process used in any particular instance is determined by the metal and the use to which its powder is to be put.

The range in processes is very wide, as can be seen by examining a few at random. The grinding process, for example, produces powders by crushing in stamp, ball, or attrition mills, and is quite simple. Brittle and tough metals can be handled in this manner, but malleable metals must be stamped. Powders so produced are flaky in form, a good example is metal paint pigment. Atomizing, on the other hand, requires forcing a thin stream of molten metal through an orifice and then hitting it with a stream of steam or compressed an. This method permits a very close control of powder size and regulation of the size at will. It is employed when powders are to be used in molded products. although copper cannot be so treated Still another process which permits close control is that of reduction from the compounds, in particular the oxides, chlorides, and hydrides, using temperatures below that which will melt the metal. Tungsten filament, as previously mentioned, is produced in this manner

ONTEMPORARY with research to develop suitable powders has gone much study in the art of compressing And here, in this second phase of powder metallurgy, are revealed many of the most striking achievements and more than a hint as to limitations. The production of metal parts or products from powders requires pressures ranging from 15 to 50 tons per square inch. Now these pressures can be obtained, as the presence of parts proves, but the surface area of pieces is very definitely limited at the moment by the mechanical difficulties of building presses which will compress large surface areas economically. Further difficulty is encountered when trying to produce parts having great thickness to be compressed. It requires a pressure ratio of three to one to do a job with proper porosity or density because the average density of the powders is about 30 percent that of the cast metal. The mechanical difficulties are complex enough, but if you try to compress metals of different densities the problem is intensified by physical consid-

There are authorities who express confidence that these problems will be solved to broaden the field of metal powder application. One specialist has said: "We can't press around a corner yet"; but he declares that striking gains in this direction are soon to be announced. Certainly the fatricacies of form achieved

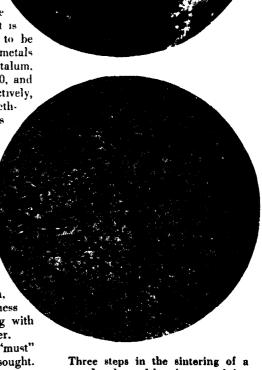

with die casting cannot be duplicated with metal powders, yet there has been steady progress and the products of today reveal an advance in complexity of form over those produced only a short time ago.

While experimenters have been trying to discover how to press large objects out of powders, they have been busy also perfecting the process of making small parts. Powders are now being produced commercially on a tonnage basis so that more and more things can be made conomically. Likewise, there have been improvements made in dies and presses so that parts can be made more quickly and with more uniformity. The speeding-up process has brought about press work at the high rate of 40 to 120 pieces per minute, using single dies. Now, with multiple dies, output can be increased substantially.

Probing the science of powder metallurgy brings two questions uppermost. Probably the reader has formulated them already. Why employ metal powders anyway? In what particular is the process superior to the older method of combining metals in their fluid state? And the second query is: What makes the particles stick together?

Our résumé of the early experiments with tungsten revealed one reason for employing powders. It is when metals are too refractory to be melted or cast conveniently. The metals of tungsten, molybdenum, and tantalum, with melting points of 6100, 4700, and 5100 degrees, Fahrenheit, respectively, cannot be handled by any other method without incurring grave troubles with equipment and losses by volatilization and oxidation But this is not the only instance where powder metallurgy makes a unique contribution. If you would make a product out of several components and wish to retain the essential identities of those components, powder metallurgy does the trick. The cemented carbides illustrate this excellently. Whether made with tungsten, tantalum, or titanium, the hardness of the carbides is retained along with the toughness of the cobalt binder.

Metal powders also play a "must" rôle when certain structures are sought. Oil-less bearings, made from powders of copper, tin, and carbon, are given a porous structure by control of pressure, while increased porosity can be obtained by an admix of volatile salts which evaporate upon heat-treating to leave pores for oil absorption. Again, this new metallurgy serves uniquely when it is de-

Three steps in the sintering of a powdered metal bearing containing copper, tin, and graphite. Top: After compression, before sintering. Light areas are tin and dark are copper. Middle: Partially sintered. Gray areas are bronze formed by interdiffusion of the two metals. Bottom: Copper and tin powders completely "alloyed" by diffusion

The three powdered constituents of an automobile bearing metal are mixed and placed in this briquetting press. The resultant solid is the actual formed bearing

sired to combine components which cannot be alloyed because of extreme differences in melting points or because of immiscibility. By surmounting this difficulty, the powder process has furnished superior electrical contact points, bearing and magnet composites, and certain welding electrodes.

THERE are many instances where powder is used by choice rather than necessity in the manufacture of metal products. Permanent magnet alloys, for example, can often be made at less expense and more easily by this process. Then there are products in which usefulness is enhanced by the higher purity possible with powder. Injury which may result from the use of de-oxidizers and de-gasifiers in the melting and casting process, can be avoided with powders.

Still another advantage is the permissibility of taking two or more metals and compressing them in layers of separate elements. By this means, composition effects can be localized. Valve parts provide a practical example.

Powder metallurgy, by its very achievements, has proved where its advantages he and has marked out the territory for exploitation. But it is still young too young to have promulgated a water-tight explanation of the mechanism of the bond. There are many theories and each may contain some truth. It is claimed that the clean surfaces of the powder permit a cohesion or adhosion of the particles under the combined action of heat and pressure. It is also thought that there is an interlocking of the metal particles because in many instances the structure of the particle is dentritic, or toothed. The action of pressure is not to be overlooked as significant in the creation of the bond.

Under pressure the air between particles is expelled and replaced with particles deformed by that pressure, giving an angularity which perhaps facilitates the union.

It has been suggested recently that the friction during compression may generate a welding heat momentarily where the surfaces are in contact. This theory arises as a result of studies on the action of metallic surfaces in contact and rubbing as occurs in bearings. Here, it developed, the friction produced sufficient heat to create slight molecular diffusion on the surface.

So the answer to the question: what makes the bond?—the greatest problem among many—must be left to the future. There are vast differences between the science of casting fluid metals and this newer one of compressing metals in the non-fluid state. Such factors as re-crystallization and grain growth, for example, are unlike and call for long study before it can be said that powder metallurgy has built a solid backlog of -cientific understanding.

Meanwhile events move rapidly. The mystery of the bond isn't holding up commercialization. Only a year ago it was thought impossible to make tool steel or high carbon steel by the powder method. Now the problem is thought to have been solved. Stainless steel, another impossibility, is declared to be a reality, while behind locked doors are other achievements yet to be released. But each and every item which becomes a reality must prove its worth competitively, so judgment as to value must be withheld. What we see happening is mainly significant to us as straws in the wind.

AT the moment, the leading application of powder metallurgy is in production of ductile metal from tungsten, molybdenum, and tantalum, and in making cemented carbide tools, porous structures, electrical contact and electrode materials. But if it is true that a way has been found to get sufficient pressures with economy for large area work, and if the complex dies now in process of development and experimentation prove satisfactory, the way will be open for the manufacture of many more metal parts and products.

Prosperity for this new process seems to be "just pressing around the corner."

THE AMATEUR'S SEISMOGRAPH

SEISMOGRAPH is neither difficult to build nor tedious to operate. Of the many forms, the Bosch-Omori horizontal-pendulum type is probably the easiest to make and maintain. To house it a small separate building is preferable, but if this is too expensive a corner of the basement will be suitable. The corner will have to be walled off to stop convection currents of air, also to preclude accidents to the apparatus As a foundation, a pier (Figure 1) should be set at least two feet in the earth beneath the floor, or on bed rock. It should have no direct contact with the floor. The zone

of earth will to some extent insulate the pier from disturbances originating with in the building. Concrete walls of base ments have also been used to support seismographs, with some success (Figure 2).

For the "heavy mass," on the pendulum, which remains virtually stationary while the earth and apparatus move, a compactly shaped cylindrical piece of metal G, weighing more than 50 pounds, will be required and a visit to a junk dealer is quite likely to reveal it already in usable form. However, as a larger mass will prove to be more effective in overcoming friction, the nearer the mass approaches 500 pounds in weight the better. A very effective seismograph can be made with a mass of 200 pounds. The mass need not necessarily be in one piece, as several disks may be bolted together, or a canister filled with shot will answer the purpose.

The mass, represented at M in Figures 1 and 2, may have its axis in the boom, as shown, or at right angles to it. The lines formed by the boom BD and the piano wire suspension AG should pass through the center of gravity of the mass. In the case of a 200 pound mass the distance BG should not be much more than one toot, while the distance to the end of the boom may be three to five feet. This will

Instructions for Building and Operating in the Owner's Cellar an Instrument which Will Record Quakes from the Most Distant Parts of the Earth

By AUSTIN E. JONES

Improving Circumstances Favor the Amateur

RETURNING from his work, a man is met at the door by that familiar refrain, "Dinner is on the table, so don't delay a single minute" He promises to "be there just as soon as I can wash my hands," and starts toward the bathroom. Then he hesitates, glances furtively backward, ducks suddenly into the cellar doorway and is gone. Time marches on. Some 211/4 minutes later he emerges breathlessly from his little seismological laboratory with a yard of grimy smoked paper, to which he points and announces with gusto to a rather disgusted waiting wife that "there has been a tremendous earthquake today and a long way off" As he eats his chilled meal he talks on and on about hig earthquakes and particularly about this one (his wife seems to be listening but is thinking about hats). When he pronounces that the quake was in the Far East those present exchange winks, but tomorrow's papers will say, "Heavy Quake Does Extensive Damage in Java'

The man is an amateur seismologist.1

For years past there has been evidence that numbers of amateurs would like to build their own earthquake recording instruments, but until quite recently there has been a lack of literature on the subject, in a form suited to the needs of the beginner. Most professional writings on seismology have been abstruse and mathematical. This situation is changing Commander N. H. Heck, chief seismologist of the United States Coast and Geodetic Survey, has published an all-around, semi-popular treatuse, "Earthquakes." Prof. L. D. Leet, in charge of the Harvard Seismograph Station, has written a detailed semi-scientific treatise on practical seismology, a book which makes available to the amateur who will do a little studying an elementary technical understanding of seismograph and earthquake principles. And now a seismologist who has built seismoaccompanying article how to make an instrument that will function for the great world-shaking, distant quakes that are chronicled in the newspapers every few days. At last, therefore, improved circumstances have made it better possible for the amateur to proceed.

The author of the accompanying

graphs for professional use tells in the

The author of the accompanying instructions (see "American Men of Science," the "Who's Who" of American science) did graduate work at the University of California, then was an assistant-scientist with the United States Geological Survey at Mt. Lassen. Later he placed two seismographs ın Alaska, and has spent four years as assistant to the widely-known volcanologist, Dr. T. A. Jaggar, Director of the Hawaiian Volcano Observatory of the Department of the Interior, where the study of earthquakes of the peculiar volcanic type is made a specialty. "A fair amount of my time," he states, "has been concerned in devising seismographs from material at hand, as well as constructing cellars for them." So far as is known, no definite instructions for making a seismograph of the quality he describes have ever been published. The professional has always purchased his instruments ready-made, or has himself employed instrument makers to make them, or else made his own, and in each case no definite huilding instructions were written out because this was unnecessary.

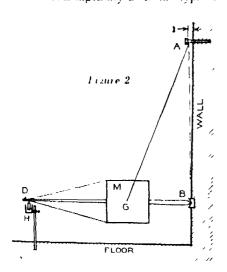

Recently a Committee on Amateur Seismology was formed in the Seismological Society of America, the national organization for professionals and interested amateurs. This society publishes, at Berkeley, California, a monthly journal named the Bulletin of the Seismological Society of America, which is not entirely technical and abstruse, many of the articles heing readily understandable by the lay reader. Other journals publish occasional articles on seismology.

Readers who construct the apparatus described here are requested to communicate their results to the editors, who are interested.—A. G. I.

¹The first syllable—sels—of this troublesome word rhymes with ice, dice, lice, be increased by a lever or pen-arm (Figure 5). When properly suspended, this mass will swing about the hinge points A and B by flexure of the piano wire.

The axis of the hinge AB is inclined to the vertical by a small angle i, which in a good set-up can be changed by a screw thread at the top of the pier. In place of the pivot-and socket joint shown in Figure 2, at B, a suspension by means of a bolt across the face of the pier, and a short wire attached to the end of the boom, as in Figure 1, will make possible another casy adjustment, but no change in period can be made without changing the angle 1 For teleseismic, or distant, work the period should be somewhat longer than seven seconds (approximately) per swing and return, but in the neighborhood of 12 seconds the pendulum is likely to become unstable. The purpose of an adjustment at B is to correct the slope of the boom, for example, in cases of tilt due to temperature, earth changes, or foundation settling

COMPLETE record of a quake, A such as the professional usually prefers for exhaustive interpretation, requires three instruments at right angles, each recording its component of waves which arrive from all directions, but any component will suffice for general interest, and in one component stations the boom is usually placed in a north-south direction. If the experimenter is not exacting at the beginning with regard to the direction which the instrument records, non adjustable ties may be made at 4 and G, and a pivot-and-socket joint made at B. It is the intention to suggest that the individual may to a great extent use his own ingenuity as to the type of

mass, boom, and adjustments. Generally the part *DM* of the boom should be light and rigid, the part *MB* being heavier and more rigid. The friction at *A* and *B* should be negligible. The smaller the mass the greater *MB* should be. However, a small mass—10 or 15 pounds, for example—would not work well unless *MB* were three or four feet long. Then

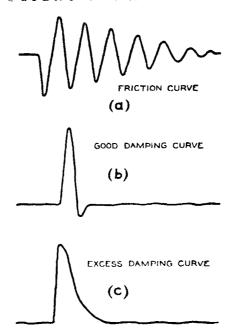

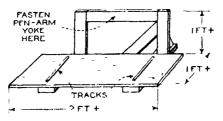

Figure 3: Some adjustment curves

DM must be short and the static magnification would be much less than with the heavier mass.

Once the pendulum is started vibrating in an arc of about one half foot, it should continue to vibrate for many minutes. If it will do that, it may be considered ready for the next step. However, while such an undamped pendulum will indicate earth movement, it will continue to move after the earth has stopped, and thus will give an erroneous indication. To stop this free movement, damping is required. Such damping, as described here, will

Tigure 4 For recording apparatus

induce the pendulum to follow earth motions fairly closely. A small amount of damping, H, at the end of the boom, as in Figure 2, will equal a larger amount near the mass, as in Figure 1. The choice is the builder's. In Figure 2 the damping would be about two square inches of vane sliding in heavy oil, or in Figure 1 many square inches. It also depends upon the size of the mass. The oil container should be adjustable in height, so that the damping will also be variable. Figure 3 shows how friction and damping affect the seismogram. When the pen is displaced it will write a decay curve, as in a. This form is due almost entirely to friction, and if the damping is increased the decay curve will be shortened. The correct damping is attained when the curve becomes similar to b, where the first displacement is about five times the second, with no third, and the

damping should be adjusted to this type of curve. Too much damping will induce a decay curve that does not recross the zone of rest but merely comes slowly back, as in c. However, the final adjustment is not made until the recording apparatus is completed.

To support the recording apparatus a wooden frame (Figure 4) may be used (though the frames of the Hawaiian Type seismograph are built of iron about 14 inch by two inches). The tracks should be built of metal rod or smoothed hard wood, so that the clock and drumcarrying frame will slide easily under the pen. The purpose of this track arrangement is to facilitate precisely positioning the drum under the delicate penarm without injury to it. The dimensions

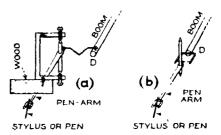

Figure 5. Two magnifying systems

shown are only approximate and may be varied. This frame will also accommodate a second pen-arm from a pendulum set up at right angles to the first, if this is later wanted as the amateur gains knowledge of seismology

The magnifying system is to be attached to the end of the boom, at D. Figure 1 or 2. The writer prefers the method of attachment shown in Figure 5, at a, consisting of cup and needle joints. The connecting link is depressed in the middle. as shown, so that it will remain balanced on the points, and is made of light, thin metal. Buttons may be soldered at the ends, in which the cups are punched. The needle on the pen-arm is placed about 1/4 mch from the pen-arm axis. As an alternative, the yoke and cross fiber method of Figue 5, b, may be used. Here again, ingenuity may assert itself. In either case the pen-arm axis is pivoted in a yoke fastened to the top of the frame (Figure 4). The magnification of the pen-arm multiplied by the magnification of the boom, BD/BM, gives the final static magnification of the seismograph. This is not the dynamic magnification. For illustration, an earth wave of 20second type records with a different magnification on a 10-second instrument than does a 3-second earth wave.

The pen-arm should be extremely light, yet fairly rigid. It is usually made of thin sheet aluminum rolled into a tapering tube (Figure 6, a) or a T-section may be bent, as in b. Approximate dimensions are ½ inch wide at the pivot or vertical axis, to ½ inch wide at the tip where the stylus is attached. The pen yoke at the tip should be very light—½

inch in greatest dimension—and may be attached to the pen-arm with wax.

The needle or stylus is a piece of fine piano wire—about No. 24 to 30—attached to an arbor from a watch, which is free to turn in dents made in the penarm yoke; or the watch bearings may also be used.

The next requirement is the works of a spring drive clock (Figure 7, a), or a

Figure 6: Two forms of pen-arm

Telechron motor, to drive a large drum d at the rate of one turn per hour. The connecting link b is constructed so that the drum axis cg will travel endwise on screw threads as it is rotated. This should record the pen motions for a day (or more if preferred), the record line spiral ling around the drum once each hour

THE drum should be large and nearly about 6 to 12 inches long and nearly THE drum should be large and light, a foot in diameter. The ends may be made of metal disks-cake tins might sufficeand the covering may be of cardboard, light wooden strips, or metal riveted on The drive end of the shaft is either square or slotted, in order that it may be turned by the clock, while the opposite end is threaded for a foot or more. If the threads extend through the drum this will facilitate fastening its ends by means of nuts and washers. For local work up to about 600 miles-the threads may be as close as 16 to the mch, but two to the inch is better for teleseisms. The drum should be three or four inches longer than the spiral, in order to allow free swing of the pen during large disturbances. In all, the axis will be about three times the length of the drum. The frame on which the clock and posts are mounted is to slide on the tracks of Figure 4

For recording, a piece of paper, smoked for each day's run, is placed on the drum. Its width should equal the length

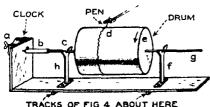

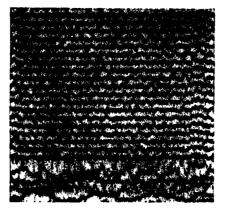

Figure 7: Drive, axis, and drum

of the drum, and it should be about two inches longer than the circumference, so that it may be folded and fastened by a small amount of library paste, as in Figure 8. While any paper will suffice, window-envelope paper has been found best. It is transparent, has a good gliding surface for the stylus, and takes paste just well enough to be easily removed from the drum without destroying its value as a record by mutilating it.

A small local portion of a seismogram showing two things: in its upper part the microseisms that shake the earth lightly but continuously and are due to pounding of the suif on the coasts of the continents, according to the most generally accepted theory, and in its lower part a portion of the record of an earthquake that originated in the Netherlands East Indies, traversed the earth, made the upper curves, was reflected to the other side of the earth and again traveled to this side to make a second record of itself (at the very bottom of the illustration). From Scientific American, Dec. 1938

For convenience in placing and removing the records it is well to have a separate supporting frame similar to the one in Figure 7, or else a wall bracket as in Figure 9, a. This frame can also be used for smoking the records. This is done by placing a kerosene lamp under the drum, which is rotated until an even coating of lampblack covers the paper. It is better, however, to build a smoking box (Figure 9, b), as a better coating is secured by its use. After the day's run the paper should be carefully removed (leaving on it not more than one or two finger prints!) and laid flat to be pinned on a hanget like the one in Figure 9, d The date and other data are written on it and it is then dipped in the thin shellac mixture in the vat (Figure 9, c). This thin shellac mixture should be about one fourth shellac and the rest alcohol Placing the storage tank lower than the vat or dipping tank will allow the vat to empty through the connecting hose and this will prevent some loss by evapora-

A defect of the seismograph just described is that no method is shown for

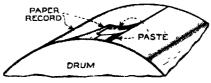

Figure 8: Simple fold for paper

recording time on the paper. This may wait until the amateur is satisfied that the seismograph is working well, for it

may require several days before any world-shaking earthquakes occur to be recorded. A good visual test of the sensitivity of the instrument is the waviness of the recording line. These waves are microseisms and their amplitude will increase in stormy weather (typical microseisms are shown in the illustration in the central column of the present page). Traffic may also disturb the record. Microseisms should have periods of from three to five seconds or more, while traffic disturbances are in the neighborhood of one second in period. Sometimes

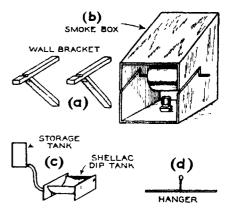

Figure 9 Accessory apparatus

traffic effect is magnified by trembling of the pen-arm, which may have nearly the same period. In such cases a small paper vane on the pen-arm often helps damp out this vibiation

The time control is maintained by a separate clock, since the added load on the drive clock would render its rate too uncertain. The second hand of the clock should be so arranged that an arm fitted on its shaft will close a contact once a minute for a period of about one second (Figure 10). The current from a dry cell will suffice to raise the pen from the paper by means of a small electromagnet

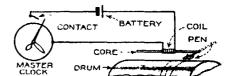

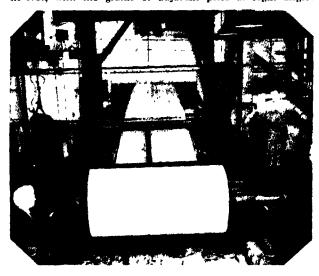

Figure 10 Electric time control

of 100 to 200 turns of magnet wire on a pencil of soft wires. This magnet is suspended above the pen by a rigid arm. The resulting gaps in the line will mark every minute of the day. To make them easier to read, hour marks can be added by contacts taken from the minute hand of the master clock. When the record is removed these latter gaps should be numbered on it with the proper hour. From time to time these marks from the master clock can be compared with radio time signals, thus obtaining for the record the absolute time correction for the beginning of each interval. This in turn will make possible the determination of the times of arrival of earthquake waves.

Removing the bark from a Douglas fir log, one of the first steps in the production of a form of plywood that finds wide use as wallboard, for structural purposes, in concrete forms, for subflooring and sheathing. Modern plywood, versatile and economical, is the result of co-operative research by forest product engineers and industrial chemists to produce a strong, light-weight material

2 Below. The log is set up in a lathe and the veneer, 1 28 to \(^{1}\)a of an inch thick, is cut in a continuous sheet that is delivered to a multi-tier conveyor. Plywood is made up of an odd number of plies bound together with various adhesives, with the grains of adjacent plies at right angles

4. Below: Veneer going into mechanical roller driers, 150 feet long. Complete drying requires 15 minutes. Plywood structure is based on the fact that wood is strong with and weak across the grain. By binding together layers of wood with grains properly placed, a composite board is obtained that is uniformly strong

From Logs To Plywood

Arrow points to aperture between lathe knife and pressure bar through which the cut Douglas fir veneer runs at high speed. In other methods of producing special plywood veneers, the thin sheets may be sliced with a long, heavy knife, or sawn from the log

Below: Veneer emerging from the driers and being placed on sorting tables. The binding force of the transverse plies in plywood practically nullifies the tendency of wood to expand or contract across the grain, thereby reducing the co-efficient of expansion of a plywood panel to little more than ½0 of 1 percent

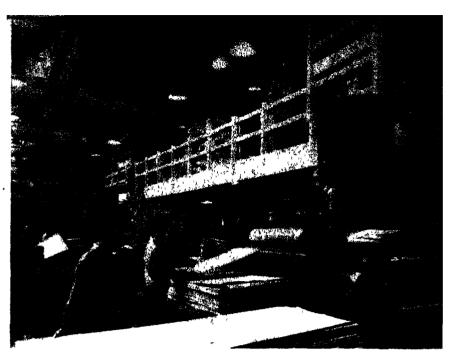

"Unwinding" Trees ... Stronger Lumber ... Made Possible by Research ... Co-operative Efforts

By A. P. PECK

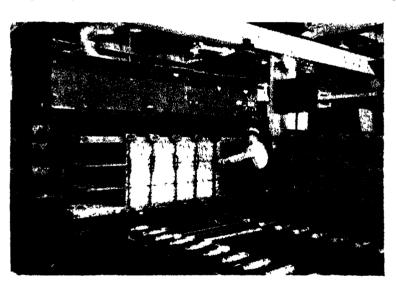

6 Close-up of the glue-spreading operation. Adhesives used are casein, phenolic resins, or soya-bean meal, according to requirements. The soya-bean meal falls into that rare category of products which are at once cheap and good. In plywoods other than Douglas fir, both vegetable and animal base glues are used

Right: Glued-up plywood is subjected to a pressure of 200 pounds to the square inch, in a hydraulic press. The I beams, rods, and turnbuckles are used to retain the pressure, thus releasing the press for use on the next batch. Note the roller-type conveyor

A general view of glue spreading showing the glue container at right center, with spreading rolls below. One of the advantages of plywood is its resistance to splitting. Nails may be driven close to the edge of the board without danger of splitting; also, nails hold well, cannot readily be drawn from plywood

9 Left: Sanding the surface of a finished, trimmed sheet of plywood. The panel passes through eight endless belt sanders, each of which carries a different grade of abrasive paper, the last of which gives a fine, smooth surface

10 Right: Finished Douglas fir plywood ready for shipment from the Seattle plant of the Aircraft Division of the United States Plywood Corporation. Trees, "unwound" and glued, are here ready for use in a multitude of applications in a wide variety of fields

The Market Country of the Country of

Sodium Skies

o clear night is really dark. Only when clouds shut out the sky altogether is there much difficulty in finding one's way in open country, and even when the clouds are heaviest it is possible to see the outline of a building or a tree against them. Impenctiable darkness outdoors is very rare, though it has happened, even at noon, during great volcanic eruptions

At first thought one would suppose that this faint illumination came from starlight. But photometric measures show that there is too much of it to be thus explained. More light comes from the vast numbers of stars invisible to the unaided eye than from those which we can see separately; but the sum of the two accounts only for about a third of the light of the night sky. A somewhat smaller part comes from the extension, all over the heavens, of the zodiacal light, that is, from sunlight reflected by an exceedingly thin haze of fine dust which extends well beyond the Earth's

orbit. But a very considerable part of the whole light originates in the Earth's atmosphere—as is shown by the fact that its strength increases toward the horizon, and so represents something carried round by the Earth's rotation

This "night sky" light shows a remarkable spectrum, consisting of emission lines and bands. It has long been known that the

green line, so conspicuous in the spectrum of the aurora, can always be seen with suitable apparatus in any part of the sky. By using spectrographs of great light-power, many fainter emissions were discovered in the blue and violet, and, in 1929, Slipher found that there were relatively powerful radiations in the yellow and red, which would be conspicuous at a glance if our eyes were as sensitive to these longer waves as they are to the green.

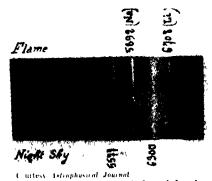

lust as the Sun's first rays at dawn strike the upper air, the conssions become stronger and new ones appear, evidently stimulated by the sunlight.

The origin of this extensive and complex spectrum has not been easy to determine fully. The light, even at best, is faint, and can be photographed only with instruments of small dispersion, so that it is not possible to separate double lines, except very wide pairs, nor to discriminate, in many cases, between individual lines such as are produced by atoms, and complex bands (emitted by

Recent Research Indicates that a Large Part of the Illumination We Commonly Designate as Starlight Originates in the Earth's Upper Atmosphere

By HENRY NORRIS RUSSELL, Ph.D.

Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Mount Wilson Observatory of the Carnegie Institution of Washington

Tigure 1. Spectrum of the night sky

Figure 2. Fringes, 0.15 and 0.30 mm, etalons

molecules), though, with ordinary higher dispersion the distinction is obvious.

Moreover, the conditions of excitation, at the very low density of the outer atmosphere, are so unfamiliar that some of the strongest lines are of the "forbidden" type which it is haid to produce at all in the laboratory. The great green line, and a pair of sharp lines in the red are such forbidden lines, emitted by neutral atoms of oxygen. Many of the bands in the blue and violet arise from neutral molecules of nitrogen Some of the strongest features in the dawn-flash come from ionized nitrogen moleculeswhich are doubtless put into condition for their emission by extreme ultraviolet light from the Sun.

Identification of many of the infra-red bands still awaits more complete laboratory studies of gaseous spectra in this region. But there is a pretty strong line in the vellow which has till recently been a great puzzle. Laboratory spectra in this region are well known; but, for a reliable comparison we must have an accurate wavelength of the line On low-dispersion plates it is very hard to secure this. The measures of several good observers, between 1929 and 1935, gave values ranging from 5885 to 5892 Ang strom units.

This immediately suggests the well known yellow sodium lines at 5889 98 and 5895 94. The spectrographs which were employed had not dispersion enough to separate the pair, and the recorded wavelength should be an average. This agrees well with the measures

of Slipher, the discoverer, in 1929, but the later values are discordant. A strong helium line is nearby, at 5875 62, but the measures do not admit of identification with this.

To settle the question, more precise measurements were required, and these have been made by a group of French observers—MM. Cabannes, Dufay, and Gauzit, of Paris and Lyon—

whose recent paper clears up the question most satisfactorily

A new spectrograph, with a camera of the remarkably high focal ratio 0.7 (that is, with focal length only 70 percent of the diameter of the lens!) made it possible to photograph the yellow line with a half hour's exposure. The dispersion in the yellow is 500 A per millimeter. The line on the plates is 1/50 mm. wide, corresponding to 10 Angstroms (enough to include both sodium lines, while the helium line, if present, would have been clearly separated). Ten good plates gave an average wavelength of 5894 ± 1 A—almost in the middle between the sodium lines.

FIGURE 1 shows one of these plates, with the green and red oxygen lines, and the yellow line. At the top the spectrum of a Bunsen flame is superposed on that of the sky. The sodium line produced by the flame agrees with the atmospheric line very closely indeed. The line at 6708 is produced by lithium in

the flame and does not appear in the sky

The critical question, however, is whether the night sky line is double. On the plates it is distinctly wider than the oxygen lines at 5577 and 6300, which are known to be sharp. Moreover, Dufay, in 1932, observed with a wide slit having a fine wire stretched lengthwise along the middle. With monochromatic radiation such as the oxygen lines, this gives a wide image on the plate with the narrow shadow of the wire down the middle; with the yellow line this shadow was less sharp.

This made it probable that the atmospheric yellow line was double, but fell short of proof. By making a spectrograph like the other, but two or three times larger in all dimensions, it should be possible to obtain spectra of greater linear dispersion, and find the line double on the photographs. But such an instrument would have been very expensive; and the analysis can be made with less costly apparatus.

The Fabry-Perot interferometer (itself a French invention) consists of two plates of glass with surfaces worked as accurately plane and parallel as possible, and set up with their inner surfaces parallel, and at a fixed distance apart. These surfaces are thinly silvered, so that they reflect back a part of the light and transmit the rest.

IF monochromatic light falls squarely upon such an apparatus, part of the light will be transmitted by both plates Another part will be reflected from the second back to the first, again by this, and then pass through. The light path will be longer by just twice the distance between the plates. If this double distance is an exact number of wavelengths of light, the two wave-trains will remforce one another -- as will also all the beams resulting from repeated reflections-and a great deal of the light will get through But, if the double distance is half a wavelength greater, the waves of the second train will interfere with those of the first-and very little energy will pass through

Now suppose that such an interferometer is set up in front of a camera, and pointed at a large luminous area which gives off light of a sharply definite wavelength. The same principle will apply; but the double distance for oblique rays must clearly be measured between the plates at the proper slant, and so will be greater, the greater the inclination. Hence, for light coming at different angles from the central axis of the plates, the device will alternately be nearly transparent and almost opaque, and our photograph will show bright and dark rings such as are exhibited in Figure 2, left, which is a negative on which the bright rings show dark.

Near the axis it takes a greater change in obliquity of the rays to increase the

path by a given amount than farther away; hence the outer rings are more closely spaced.

If two radiations of slightly different wavelengths are present, there will be two sets of rings, of different sizes. If the double distance of the plates is such that one set of light-waves gets ahead of the other by a whole wave, in traversing it, the two systems of rings will be

Figure 3. Upper cut is less oblique

superposed, but if the gain of one set of waves on the other is half a wave (or $1\frac{1}{2}$, $2\frac{1}{2}$, etc.), the second system of rings will be half-way between those of the first.

For sodium light the second situation occurs if the plates are 0.15 mm apart, and the first if their distance is 0.30 mm.

Figures 2, left and right, show the results obtained with these plate separations. The left hand halves representings obtained with sodium light in the laboratory, and the faint right-hand parts those with the night sky.

The latter show the coarse grain incivitable (with present technology) in very fast plates, but it is evident that the ring systems are essentially just the same in both cases. When the two ring-systems are seen separately (Figure 2, left), those of one set are fainter than the other, both in the sky and the laboratory —corresponding to the fact that $\lambda 5890$ is stronger than $\lambda 5896$

The agreement of the photographs makes it quite certain that the yellow radiation of the night sky actually comes from sodium

To obtain these interferometer photographs was a real tour de force. The light of other lines in the night sky spectrum had to be got rid of. The green line was cut out by an orange filter, the red line by using plates not sensitive in this region. To obtain clear photographs from the night sky exposures had to be made on two or three successive nights. At the beginning of dawn (or at a corresponding hour in the evening) the radiations are much stronger, and exposures of half an hour suffice Figure 2 represents photographs taken in this light The longer exposures during the night gave substantially the same result. The intensity of the yellow lines is greater at low altitudes in the sky than near the zenith, obviously because we are looking through a greater thickness of faintly luminous atmosphere in the second case. If radiation comes from a fairly thin layer at a definite height above the ground, this effect will be greater, the less the height. It is obvious

from Figure 3 that the line of sight cuts the upper layer less obliquely.

From measures made by Garrigue, our authors conclude that the height of the luminescent layer is about 130 kilometers, or 80 miles.

This beautiful piece of work shows conclusively that sodium atoms are present in the upper regions of the Earth's atmosphere in sufficient abundance to give out their characteristic radiation This is a very extraordinary fact, for there are also oxygen atoms up there, as well as molecules, and a free sodium atom would seem to have little better chance of long life than Billy Sunday's famous "celluloid dog chasing an ashestos cat through Hell." At present we can only say that they evidently do last long enough to do a good bit of shining. In the regions exposed to sunlight these free atoms cannot help absorbing energy from sunlight, and unloading it again, giving the characteristic "resonance emissions" The sunlight which they are absorbing is represented by the centers of the observed sodium lines, and is much weakened, but still pretty strong, so that it is easy to see why these lines show so strongly at dawn. In the middle of the night they may be excited by impacts of electrons or ions--which are known to be present at this height.

BUT how do the sodium atoms get there? It is imaginable that some minute amount of salt dust derived from ocean spray may get a few miles up but if it did get 80 miles high, we would have molecules of NaCl, and no known way of decomposing them.

Our authors think it probable that the sodium comes from meteorites, which certainly contain sodium and are volatilized, in great numbers, at about this height. While the meteor is luminous it is very hot; and it is reasonable enough to suppose that free sodium atoms may escape from the turnoil.

If this explanation is correct, there should be free calcium atoms present, too,-and our French colleagues note that a faint line in the night sky spectrum at \$\darkappa 4226 coincides, within the er-101s of measurement, with the resonance line of calcium. The meteorites should also liberate atoms of aluminum, potassium, iron, magnesium and silicon; but the resonance lines of the last two are out of reach in the ultra-violet-obscured by ozone absorption. Those of iron and aluminum are in the accessible portion of the ultra-violet, and therefore might be detected by observation in this region. The potassium lines are in the deep red, and might be disentangled from the strong bands there. Further studies which are being made in this promising field will be of great interest .- Princeton University Observatory, December 5, 1938,

American Archeologists

MGHT years of excavation in the Agora of Athens, conducted by the American School of Classical Studies, have resulted in uncovering the greater part of the ancient market place Where 360 modern houses stood in 1931, and narrow streets were teeming with thousands of local residents, there now appear the public buildings and the broad streets which were frequented for hundreds of years by Athenians of the classical period. Since the level of the terrain of that age lies between 10 and 15 feet below the modern level it has been necessary to remove 190,000 tons of earth, which have been carted to the outskirts of the city where low land re-

Athens was subjected several times in its history to thorough devastation by invading armies: by the Persians in 480

quired to be filled.

Recent Results of the Excavation of the Agora, Market Place and Civic Center of Ancient Athens, Have Exceeded All the Previous Expectations

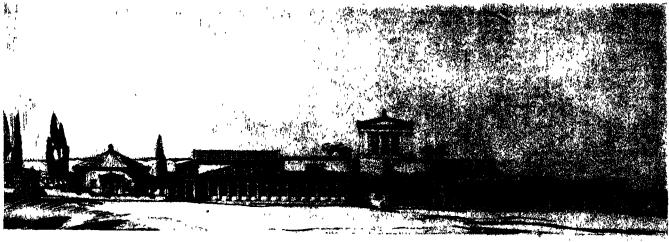

B.c., by the Romans under Sulla in 86 B.C., by the Herulians in 267 A.D., and by the Goths under Alaric in 396 A.D. Moreover, the site of the city has been almost continuously occupied from ancient to modern times. The result is that the remains of the ancient buildings exist for the most part only in foundations, but in the débris from the various destructions lying about the foundations so many architectural pieces from the superstructures of the buildings have been recovered as to make it possible to reconstruct the buildings on paper with practical certainty

The identifications of the public buildings are based on references to them by ancient writers, among whom the most valuable is Pausanias, a traveler who visited Athens about the middle of the second century after Christ. Although Pausanias did not aim to write a guide book, his description is so lucid that the excavated buildings can be exactly equated with those listed seriatim in histinerary. We can thus follow in the visitor's footsteps along the street bordering the west side of the market and see the Portico of Zeus, where occurred the diverting colloquy on feminine beauty be-

tween Socrates and Ischomachos, the small Ionic temple of Apollo, the Temple of the Mother of the Gods, where the archives of the city were filed and in the court of which the cask of Diogenes lay, the Senate House, and finally the Tholos, a circular building where the officers of the Council were boarded and distinguished foreigners were entertained. Towering on a hillock above these ruins is the best preserved of

At left: A fraction of the excavations; Temple of Hephaestus. Below, left to right: Tholos, Temple of the Mother of the Gods, hehind it the roof of the Senate House, a stair leading to Temple of Hephaestus, the Temple of Apollo, the Stoa of Zeus Eleutherius

IN ANCIENT ATHENS

By T. LESLIE SHEAR

Professor of Classical Archeology at Princeton University Field Director of the American School of Classical Studies

The vase mending room mentioned in the text, with thousands of potsherds, or fragments of broken vessels, spread out on the tables in systematic order

all Greek temples, which has now been proved to have been dedicated to Hephaestus, the God of the forge.

Still following the route of Pausanias we then pass to the Temple of Ares, north of which is the Altar of the Twelve Gods, the most sacred altar in the market place; in the center of the area is the Odeum, in the southwest corner the main fountain house of the city and along the east side runs a broad street, 30 feet wide, which for centuries was the chief thoroughfare from the Agora to the Acropolis, providing an easy ascent for the great Panathenaic procession which regularly paused half up the slope at the site of the Eleusinion.

Thus the topography of the market place, as it appeared in the classical period, has been almost completely revealed, but in addition to that the excavations have uncovered earlier buildings and monuments which were unknown to the classical Greeks and have brought to light a long series of subsequent settlements. Substantial remains have been found of continuous occupation of the site extending with little interruption from the late neolithic age, about 3000 B.C., down to modern times. In order to determine the relative ages of successive deposits the utmost care must be exercised in the observation and excavation of sumerous superimposed strata, and the objects found in them, by which the

chronology is fixed, must be accurately identified and precisely recorded. To this end a group of expert excavators has been developed in the Agora work and an elaborate system of recording has been established by which any one of the 38,000 catalogued objects from any designated square meter of the site at any stated level is immediately available.

BEFORE the beginning of these excavations it had been generally prophested that, because of the thorough devastation of the area, little of other than topographical and historical interest would be found except inscribed records which, being on stone, would not have been coveted by invading conquerors. The epigraphical haivest has, in fact, exceeded all expectations. The 5500 inscriptions so far found include part of the law code of Solon, the official list of the confiscated property of Alcibiades, other important legal documents, dedicatory inscriptions of various kinds, among which the most important are the epigrams of Simonides and Aeschylus in honor of the Athenians who fell at Marathon, and the epigram by Simonides written on the base of the statues of the Tyrannicides. Many honorary decrees which carry their date of issue have furnished much information in regard to names and dates of the archons of Athens, so that important additions and

Vase of late 6th Century, found in a well in center of the Tholos

corrections have been made to our knowledge of the Attic calendar. Not the least important of the inscribed documents is the collection of 289 ostraka, the ballots cast against citizens whom their fellows wished to drive into exile. The list includes the first and last men ostracized, Hipparchos, son of Charmos, in 487 B.C. and Hyperbolos, son of Antiphanes, in 417. The man on the list with the largest number of ballots (99) is Themistocles, and next to him comes Aristeides, "the Just," with 49 votes. These ballots are contemporary documents and, apart from their historical value, are of interest in illustrating the orthography of the average Athenian of the time.

A surprising result of the excavations is the discovery of sculptured works of both Greek and Roman periods and of quantities of vases, many of which are preserved in perfect condition. The unexpected sources of this material are early graves and wells, which were filled from time to time with débris, usually due to the clearance of the site after some disaster to the city. Since burials were not permitted within the city limits the graves antedate the period when the market place was here located. Scattered graves have been found with their contents intact which date from the late neolithic period, about 3000 BC., from the Mycenaean, 1200 a c., and from the protogeometric age, 900 B.C. Besides these a family burial plot, located just south of the later Tholos, was uncovered which dates from late geometric times (8th Century B.c.). The plot contained shaft graves for adults and urn burials for infants; its homogeneous nature was indicated by the proximity of the burials and by the fact that the area was surrounded by a circuit wall. Moreover, a detailed anthropological investigation of the skeletal material revealed a strong

family resemblance among the occupants of the graves. The graves, which were intact with their stone covers in place, yielded many handsome complete vases of the period, one burial, that of a young girl, containing no less than 28 objects. This plot had been completely covered by the beginning of the 5th Century and its existence was presumably then unknown. It is evident that these

Vase of early 6th Century found in a well, showing oriental influence

graves have been preserved only by accident and that many other burials in the area were destroyed when the rock was cleared for the massive foundations of later buildings.

The most fertile source for individual objects has been the deposit in wells These are invariably cut in the soft bedrock and extend down to varying depths. the deepest so far cleared having a depth of about 120 feet. A few of the wells have been used continuously to modern times. but most of them are filled to the top with earth and débris. In some cases the ancient diggers failed to strike water and abandoned the project, but usually water is encountered after a few yards of upper filling has been removed, and several times the inflow of water has been so great that a 24-hour schedule of bailing has been necessary in order to make possible the removal of the deposit. Some wells have been opened on the northern slope of the Acropolis and in the Agora itself but most of them served small houses and shops in the areas adjacent to the market place.

THE clearance of a well is a difficult technical problem since the diameter of the shaft rarely exceeds a yard and is often less, and great care must be exercised in order to avoid breakage of fragile objects. A skilled workman of small size works in the shaft, using only his hands for digging when small objects are numerous in the earth. The water and earth are removed by metal buckets operated by a windlass, and the deposit is recorded at 50 centimeter levels, the strictest watch being kept for evidence of stratification. All earth from wells is

passed through a sieve at least once; that from the well containing the ivory statuette of Apollo Lykeios was sifted three times.

The wells were filled up at different periods, usually in connection with some devastation of the city, such as the Persian invasion or the sack of Sulla, It may have been fear of pollution that led surviving inhabitants to fill existing wells with débris and hew in the solid rock with considerable effort new ones nearby. Where wells have been in actual use complete vases, usually of undecorated household ware, are invariably found at the bottom where they have fallen from the hands of careless housemaids. But for the most part the pottery in the filling deposits is broken and these potsherds, sometimes exceeding a hundred baskets in quantity, are taken to the workrooms where, arranged in sequence of depth from the top to the bottom of the well, they are spread out on long tables. Then

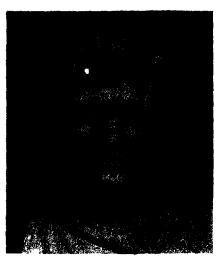

Staff members and technicians mending vases in the workrooms

members of the staff and the Greek technicians sort pieces belonging to individual vases which are put together, with restorations in plaster of any missing pieces.

Since the dates of the construction and of the filling of a well can usually be closely fixed by the pottery, lamps or coms on the respective levels, it is evident that invaluable chronological data are provided for other associated objects of which the exact period was previously unknown. If, for example, a piece of sculpture is found in a well which contains nothing later than the sack of Sulla. as occurred last season, that sculpture cannot be interpreted as a Roman copy of a Greek work, Similarly, in the case of undecorated household pottery and kitchen ware, which has been largely disregarded in the past, deposits of fixed date acquaint us with the domestic habits of the Athenians throughout the ages. A considerable amount of this plain pottery was secured in the last campaign from a well in the center of the later Tholos, which was constructed in the third quarter of the 6th Century and went out of use in 480. It was associated with handsome black-figured vases of the late 6th Century. This was the table ware which was undoubtedly used in connection with the service of meals in the Tholos to the officers of the Council.

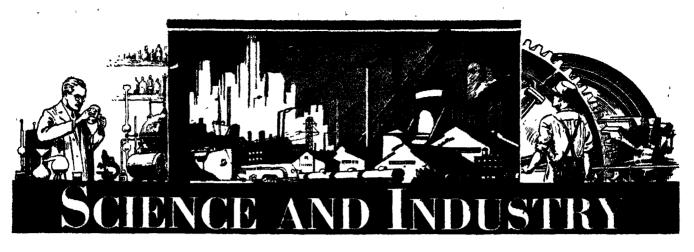

NOT a few pieces of sculpture have been secured from wells and in several cases where the pieces fit together to form complete statues it is clear that the objects were deliberately broken at the time they were thrown away. The most sensational discovery in the field was that of the unique ivory statuette of Apollo Lykeios which has been put together from 275 small pieces. A marble statue of a Faun was found broken in 73 pieces, and during the past season a statue of Hermes (see below) proved to be intact except for the right hand, after seven pieces had been cemented together. Occasionally the despoilers dumped an object into a well without taking the trouble to mar it, and then the excavators are cheered by the discovery of a handsome work such as the marble head of the bearded Hermes of archaic type, found also in the last campaign. This is a beautiful replica of the Hermes of Alcamenes, a sculptor who was active about the middle of the 5th Century B.c. Bronzes as well as marbles were tossed into the wells but, with several notable exceptions, they have suffered serious damage from the corrosive action of the water. The wells thus served as convenient dumping places for refuse, cast-offs, and any ob-

The head of the statue of Hermes which was found in a well in 1938

jects of which contemporary inhabitants wished to be rid, human nature being the same then as now; they have proved to be exhaustless mines of treasure to the excavators.

All the objects from the excavations are housed in a temporary museum on the site which will be replaced by a permanent Agora Museum, the construction of which will be begun in the immediate future. Full reports on the progress of the work and on the many discoveries are published in preliminary form in Hesperia, the Journal of the American School at Athens.

A MONTHLY DIGEST

LARGEST STEAM HAMMER

RAISING its steam cylinder-head higher than the average dwelling house, the largest steam drop hammer ever hull has been shipped to England from the Eric Foundry Company. This hammer will be used in the forging of airplane engine crankcases and airplane propellers for British aircraft of all types.

So light is the control that the ram may be brought within the smallest fraction of an inch of the dies at full speed and stopped there. The cushion effect of steam control was a marvelous sight to watch as the hammer underwent its preliminary test before being dismantled for shipment.

After installation, the hammer will be 27 feet in height, from the floor line to the top of the cylinder. Beneath the floor, extending 12 feet 9½ inches into the ground and resting upon its own foundation anchored to bedrock, extends the sub-anvil structure. This is in two pieces, each of which weighs approximately 234,000 pounds. The super-anvil, above the floor line and support-

ing the gigantic frames, is in two pieces, each of which weighs approximately 200,000 pounds

The weight of the ram, piston rod, and piston is 50,000 pounds, and with the top die included, the reciprocating weight in creases to more than 70,000 pounds. The diameter of the cylinder is 39 inches and the stroke of the piston is 72 inches. The piston rod diameter is 11½ inches. The space between the guides is 50 inches and the ram is 80 inches front to back.

WINE FROM MILK

BECAUSE the great dairy industry in Denmark has whey as a by-product of its operations, carnest efforts have been made to find uses for the quantities of this liquid wasted. One of the latest results of these researches is the manufacture of an excellent "wine" from whey. So far only in the large-scale experimental stage, the process may yield as much as a million and a half Danish kroner annually, if results as proved to date can be realized on a nation-wide scale—D H. K.

X-RAY "CANDID CAMERA" SNAPS HUMAN CHEST

A SMALL glass "trigger tube," no larger than a 65-watt lamp, puts ordinary house current to work snapping a candid-camera picture of a human chest in less than a hundredth of a second.

This tube controls the flow of 110-volt power from a light-socket to a bank of condensers. Eight seconds later, at the press of a button, it releases this stored-up power as an 89,000-volt maximum discharge through an X-ray tube.

The resultant invisible X rays are shot out from the large tube and through the chest of a model standing four feet from the port-

Taking an X-ray snapshot

able machine. Clicking faster than a heart beat, this latest development in candid picture-making recorded a chest radiograph free from distortions which the movements of the heart sometimes cause in conventional X-ray pictures.

Dr. Victor E. Hicks, director of the industrial division of the Westinghouse X-Ray Company, recently explained that the new condenser discharge dynex had been de-

veloped primarily for the study of chests in medical practice and listed its outstanding features as "the elimination of mechanical time switches, plus the uniformity of the chest films produced regardless of the chest thickness or line voltage variations."

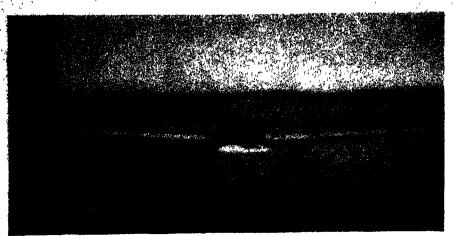

The "trigger tube," Dr. Hicks continued, is a vacuum tube containing electric coils, which permits the power to flow from the electric outlet to the condensers and then when the coils become heated permits the condensers to discharge their accumulated power to make the X-ray exposure.

TINTED INSULATION BOARD

THE insulation board industry, whose first products were strictly utilitarian, has long been seeking to make its products decorative as well. The boards made of wood fibers, first a deep brown, have steadily been lightened in color, and are now available in a light tan.

One of the most spectacular advances,

· 1915年17月1日 1755年1

however, has come in recent months with the perfecting, by Fir-Tex engineers, of a tinting process. Fir-Tex "Colorkote" panels now are offered in ivory, sky blue, apple green, apricot, and shell pink. They provide interior wall finish, and insulation, in one application. Eliminated are lath, plaster. wallpaper, and calcimine.

The basic board is made of interlaced wood fibers. The manufacturing process utilizes the by-products of Pacific Northwest lumbering—clean, inside wood which, for ordinary building purposes, is the wrong size or shape. The special Colorkote preparation, containing the desired tint, is mechanically painted on the board. In a battery of dry kilns, the tint preparation is baked in A calendering operation then produces a glazed surface.

Since the coloring material is insoluble in water, the Colorkote panels are washable. The home owner may change the color scheme at any time. Any decorating treatment may be used, and no sizing is required For novelty effects, the panels may be grooved to reveal the natural tan color be neath.

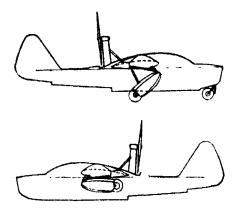

A Novel Amphibian

THE Spencer-Larsen Amphibian, which has been undergoing extensive tests on Long Island, has many novel and logical features in its design

In a pusher flying boat, the propeller thrust line must be well above the top of the hull, and so the heavy engine is likewise placed high above the hull. The center of gravity is high accordingly. But for stability in the water, the center of gravity should be low. The designers of the new amphibian have reconciled these divergent requirements by putting the engine in the hull and driving the propeller through a gear transmission unit, using two vertical shafts. If the welldesigned transmission system proves entirely serviceable, positioning the engine within the hull will bring other advantages such as the elimination of a drag-producing nacelle and greater efficiency of the propeller, which will be free of interferences. Of course the cooling of the internally placed engine must be carefully taken care of and suitable air scoops must be provided.

In former years, plywood was regarded with suspicion when employed in the hull, In the Spencer-Larsen machine, however, phenolic bonded plywood, internally protected with Bakelite varnish and externally with synthetic enamel, has resulted in a seaworthy hull which is easier and cheaper to

Above: The Spencer-Larsen amphibian. Below: Drawings showing how the stabilizing floats and landing wheels are combined and pivoted so the wheels may be retracted

build in limited production than a metal hull.

The amphibian characteristics have been attained by making the two stabilizing floats and the landing gear into single units. When the front end of each float is pivoted upward, the main wheels are in contact with the ground, and the nose wheel is let down. The boat is then provided with a perfectly serviceable landing gear. But when the nose of each float is depressed, the wheels are raised simultaneously and are faired in behund the floats. The photograph shows the general lines of the amphibian; the sketches illustrate the functioning of the combined water and land alighting gear.

With a four cylinder Menasco engine developing 125 horsepower, two occupants, and a useful load of 600 pounds, a respectable cruising speed is obtained. A small, not too expensive amphibian is not available on the market at the present time, and intelligent efforts to fill the gap will be welcomed by the aviation fraternity,-A. K.

CHAIRMAN OF THE C. A. A.

DERSONAL contact with Edward J. Noble. Chairman of the Civil Aeronautics Authority convinces us that here is the right man for an important job, Mr. Noble is not a career bureaucrat, not an over-zealous reformer, but a quiet, capable business man, with the most sincere desire to advance American aviation. He is modestly studying every phase of the many problems facing the Authority and coming to careful, wellthought out decisions. Every announcement coming from the Authority in Washington bears out this view. Thus the solution of the vexing problem of a real airport for the capital of the country, and the elimination of the terrible flight hazards at the Washington airport, are both in sight. Plans are under way for a 750-acre airport at Gravelly Point on the Potomac River, only three and a half miles from the Washington Post Office. Four runways of at least 5000 feet each, good approaches, freedom from danger of flooding, and excellent navigational facilities are all to be provided. Again, the Civil Aeronautics Authority is not rushing into a program of airport construction for the whole country, but is undertaking a careful and comprehensive rational survey first of all .- A. K.

AUTOMATIC DIRECTION FINDER

FTER several months of intensive flight A testing in scheduled service with an American Air Lines Douglas transport plane, the Sperry Gyroscope Company has made public announcement of its new automatic direction finder, Since November, 1937, air regulations have required that all transport planes should be equipped with a shielded loop antenna and a direction finder to help locate the airplane and to secure positive radio reception of the airway beams under adverse weather conditions. Many excellent devices have been put into service and have proved of great utility.

The only drawback to these devices has been that they require close attention by the pilot, already burdened with other duties. The new direction finder not only achieves what previous devices have achieved, but functions automatically and continuously, to the great relief of the airman.

With the automatic direction finder, the pilot is only required to tune to a station. The pointer on the dial of the instrument indicates the exac bearing of the station and continues to give the bearing even up to the point of passing over the station, Another valuable feature of the device is that it immediately shows the pilot when he has passed over a station, to confirm the "cone

The indicator of the automatic dir tion finder is conveniently le

of ellence" which he may have a flying on the regular radio beam silence is recognized in a sitive sid, since, as the form it a momentary shades of my a Another advantage of the m

that it provides a method of determinis

defit or "crab" angle at any time. The pilot can tune in on a station toward which he is flying and observe whether or not the heading of the sirplane is constantly changing. If he then turns the airplane to right or left until the bearing is no longer changing, he can determine, by a simple arithmetical process, the angle of drift or "crab" that the plane must take to make allowance for the wind.

Still another advantage is that bearings can now be obtained when static conditions are so bad that it is virtually impossible to obtain a "null" signal if operating the ordinary type of hand-operated loop.

The instrument is so mounted as to have considerable appeal from the point of view of convenience. As our photograph indicates, the centrally located automatic direction finder is mounted in a horizontal plane. Following the pointer, the pilot can readily imagine what his course and bearings are over the earth below.

Some marvellous things have been done in demonstration. For example, the Douglas plane was able to locate a carefully hidden truck which was acting as a temporary transmitting station—A. K.

THE LIBRASCOPE

NE of the most important points in airplane operation is the correct balance or trim of the craft. Yet changes in cargo, consumption of fuel, changes in position of the passengers, all introduce changes in the trim. Minor variations in the center of gravity position may be taken care of by the use of tabs or trimmers placed at the rear edges of the elevators. But the tabs must not be asked to do too much or else both efficiency and control power are lost. Also, it is far better to know the location of the center of gravity at all times, so that necessary adjustments in weight position can be readily made. Formerly the operating personnel was provided with elaborate loading charts, and had to carry out complex computations.

Now the job has been taken over by the Librascope, made by the Meredith Instrument Company, which has no friction devices or springs to wear or deteriorate and carries on its lower face a number of dials which indicate (as our photograph shows) landing gear position, the amount of oil and fuel in the tanks, ballast, passenger loads in various seats, cargo load, and so on. By moving the various knobs appropriately, and setting

A seaplane on the Friesenland's catapult

the weight adjustment to work, the operator can read the total weight on the scale at the upper left hand corner. A change over to "balance adjustment" indicates the center of gravity position on the right upper scale. We have operated the instrument our-elves at Newark Airport, and have been satisfied that here is a simple, entirely practical, and highly useful device.—A K

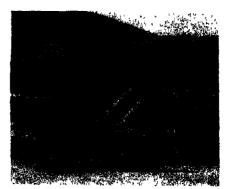

CATAPULTING A LARGE SEAPLANE

THERE are many plans for commercial operation across the North Atlantic: the composite seaplane, the construction of a seadrome in mid-Atlantic, the use of a very fast, very clean landplane; the utilization of large flying boats with stopping places at the Bermudas or the Azores; the catapulting of heavily loaded scaplanes. We believe that the final solution will be in the construction of very large flying boats which will be able to fly non-stop from New York to London. while carrying a commercial payload. But in the intermediate stage, the catapulting of a large scaplane from a mother surface vessel, as practiced by the Deutsche Lufthansa, is an effective and successful method of operation. Recently the writer of these notes had the privilege of visiting the Friesenland, a surface vessel which is employed in catapulting the Lufthansa's seaplanes, and of observing the launching process. German engineers have worked out

the catapulting system in good fashion. An air compressor, electrically driven, supplies air to huge cylinders with slow moving pistons. The irresistible power of the pistons, acting through sheaves and cables, sets the carriage into rapid motion without perceptible effort. The plane moves over the onlooker's head and in a couple of seconds the huge seaplane is aloft and away. Even the most blase spectator gets a thrill when witnessing this triumph of the mechanical engineer's art —A. K

TORTURING THE LANDING GEAR

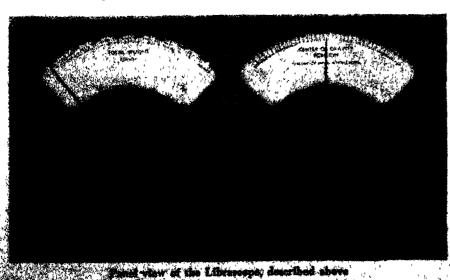

IN sirplane construction the ships are subjected to severe loading tests, to destruction if necessary, but it is not possible to submit them to quite the same degree of

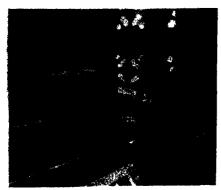

Landing gear torture unit

rough testing as is done with automobilesthe hazard to pilots would be too great. Nevertheless, aeronautical engineers are rapidly developing a technique which will give guarantee of strength and safety in the completed ship. Thus, Lockheed Aircraft has recently introduced a piece of test equipment for landing gears which is a decided addition to this art of destructive or preventive testing. The three-wheel landing gear, of the tricycle or nose wheel type, is towed behind a car. On the three wheels is mounted a rather fantastic looking structure, on which the brave test pilot takes his scat, and on which tons of pig iron can be distributed in various ways. The wheels are provided with airplane brakes. Here are me of the test methods which the engineers

While rolling along at 40 to 45 miles per

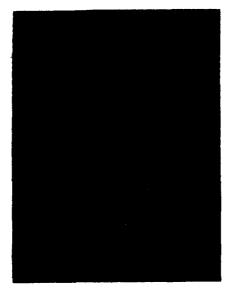

Above: Loudspeakers in the belfry, and, right, the chime amplifier. The chimes themselves are concealed behind a set of dummy organ pipes

hour, the pilot suddenly locks one rear wheel brake. The three tons of steel framework and pig iron swerve sharply, rock, but do not turn over.

At the end of the runway a steel plate is placed on the ground It is about 12 feet long, ten feet wide and heavily greased so that it is as slippery as ice. The tow car reaches a very high speed, and releases the tricycle landing gear just before the greased plate is reached. The pilot bounces the machine on the rough terrain, raises the front wheel and, while it is off the ground, turns it sidewise. On landing, then, it is in exactly the opposite position to that which all good landing wheels should assume for a proper landing. Violent "shimmy" is thus induced, and the pilot is subjecting the gear to the most severe test possible. The muchine bounces, jolts, and then to top off, skids onto the greased plate at 35 miles per hour. The front wheel swings around and the gear resumes normal operation, rolls ahead, and comes to a stop. That is to say, it should, if the designers have done a good job. Otherwise, the landing gear goes back to the ex perimental shop, and the pilot probably to the hospital!-A. K.

To Popularize Private Flying

RUMOR has it that the Civil Aeronautics Authority is seeking a method of stimulating private flying, but there is no inkling of the precise plan to be employed. In the meantime we have learned of the proposal of Alfred B. Bennett of the Bennett Air Service which has been well received in aviation circles. Mr. Bennett proposes that the Government should pay a student pilot \$50 when he solos and \$50 when he has had ten hours of solo flying. With the modest rates of flying instruction now available on Taylor Cubs and other low-priced aircraft,

the process of learning to fly would thus cost the young aviator practically nothing.

This plan would lead to an enormous increase in the number of student pilots. Thence would follow an equally large increase in the number of small airports, and an important increase in the construction and sale of low-priced airplanes.

In time of war there would be an enormous reservoir of pilots from whom to select the men capable of mastering the art of piloting a 300-mile-an hour pursuit plane. With the dangerous and continued unbalance of the Federal Budget, every responsible citizen is loath to suggest any scheme, however meritorious, which involves an increase of public expenditures. But of all the propounded pump priming plans this appears to be one of the most meritorious.—A. K.

EMPTY BELFRIES

A SYSTEM of amplified chimes installed in an eastern church appears to have solved the problem of the empty bell towers in American churches. This system utilizes

as its source a set of 21 standard tubular chimes such as those used by musicians. These are played from a small keyboard attached to the organ console and their sound is picked up by two microphones, placed for properly proportioned pick-up. These are standard crystal microphones and are fed into the mixing panel of a 250-watt amplifier developed for this service by Transformer Corporation of America. The heavy duty, horn-type loudspeakers, four of which are mounted in the bell tower, are fed through a low-impedance line and are capable of handling up to 160 watts output.

Centrally located in a city which has an area of approximately ten square miles, it has never been found necessary to operate the system at full capacity. In fact both the amplifier and the loudspeakers provide more than ample reserve to take care of the surges which are characteristic of the initial "hammer thump" of the chimes, a feature which received the special attention of engineers in the design of the amplifier.

So realistic is the sound reproduction of this system that only a handful of the populace is aware that the church tower does not house a genuine carillon consisting of massive bells.

This is one heretofore empty bell tower that has been utilized to the entire satisfaction of everyone concerned—and at a very small fraction of the expenditure that would have been involved for genuine bells

CORROSION PROOF

MORE than five tons of Monel nuts, bolts, and special studs are being used on the Fort Peck Dam project, North Dukota, as fusteners for valve seats and rings.

New Continuous Process for Propucing Rayon

A NEW continuous process for the production of rayon, still America's fastest growing textile fiber, recently went into large-scale commercial use with the opening of a huge plant by the Industrial Rayon Corporation at Painesville, Ohio. The plant will produce 12,000,000 pounds of complete ly processed rayon yarns per year.

Starting with cellulose sheets at the top.

Viscose ripening tanks and reel frames in the new continuous process rayon plant

the process finally winds completely finished rayon threads, ready for delivery to textile mills, on bobbins set low on the floor. Differing from conventional procedure, the rayon is not spun and wound on the bobbins immediately after being formed, but is bleached, shrunk, prepared, dried, and twisted before being wound.

Six years of research are represented in the plant, built at a cost of \$11,500,000. A pilot plant has been in operation successfully for two years. Fourteen acres of floor space have been provided in the buildings of the windowless air-conditioned plant. Daylight enters the factory through glass wall panels and monitors of glass block, 371,000 of which have been used in the factory, the laboratory, the power house, and auxiliary structures which, together, represent the largest glass block installation on record.

Special machinery for handling the rayon in this new fashion was developed by a subsidiary of the company. More exact conformation to specifications is one of the advantages claimed for the process.—Science Service.

Non-Flood Device For Batteries

A NEW non-flood device for automobile storage batteries, to meet problems created by the modern practice of putting the battery under the hood, has been developed by engineers of The B. F. Goodrich Company. According to the manufacturer, a battery equipped with this device removes all fear that costly damage will come to engine parts through over-filling.

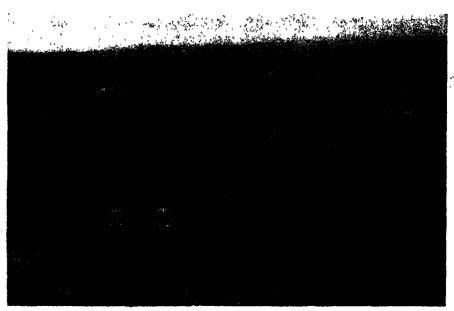

Three hard rubber parts—a barrel with two air vents, vent cap, and specially designed cell cover—make up the assembly. The barrel is screwed into the under side of each cell cover before the battery is assembled, a flange making it irremovable through the top of the cell cover when the battery is ready for service. A slotted top is provided in which the vent cap slides sidewise when being removed or replaced.

In operation, the barrel moves up when the vent cap is unscrewed and at the same time the two air vents located on each side of the barrel are closed, trapping air within the cell. As water is added, the air is forced to the top of the cell and when the electrolyte level reaches the bottom of the barrel, the air pocket beneath the cell cover prevents further addition of water.

At this point, scientifically determined, a small amount of water collects in the barrel, indicating that the safe filling level has

Below and right: New non-flood battery cap, showing how it works,

For carrying explosives to remote oil-field locations

been reached, with the non-flood device assuring sufficient space within the cell for the electrolyte to expand.

The barrel is firmly anchored, and holds the vent cap securely in place when the cap is screwed down. Air vents are opened, the trapped air escapes, and the water remaining in the barrel flows freely into the cell, without bringing the battery solution above the safe level

JUST WAVE THE MAGIC WAND

THE physics principle discovered by the scientist who rubbed a stick of amber with wool and made cat's fur stand on end is used as the operating force in an interesting toy airplane manufactured by The Mystoplane Company. Simply at the wave of a wand, tiny aluminum airplanes are made to remain in the air for several minutes, executing strange gyrations and flying formations.

The "Mystoplane" Set consists of a hard

rubber wand tipped with aluminum, a wool rubbing cloth, and a generous supply of tiny aluminum foil airplanes. The wand is rubbed with the cloth until a negative charge of electricity is stored up in the rubber, then one of the airplanes is touched with the wand, receiving a similar negative charge. Waving the wand then in the vicinity of the nirplane repels the tiny ship and causes it

to climb, dive, bank and turn, and behave like an actual airplane.

We predict that a lot of happy children are going to have a lot of fun watching Papa caper around the living room chasing a hunk of aluminum foil with a club.

TEN TIRES FLOAT OIL EXPLORERS

M AN makes earthquakes to order in the crude-oil explorations which grow more scientific every day. These earthquakes are set in motion by explosives, so their reflections from subterranean layers of pre-historic rock can be measured in nearly a dozen ways

Since the ancient rock formations that might pocket a hidden oil fortune occur as often under impassable Louisiana swamps as they do under the paved streets of Texas towns, man was compelled to devise a means to overcome marshy hazards.

These swamps were literally impassable to humans until swamp buggies, such as the Continental Oil Company explosives truck shown in our photograph, were built. This swamp buggy actually floats its weight of several tons over the "bottomless" mire on luge Firestone Ground Crip tires. Of course, the tires are kept at a low air pressure to cushion the truck's testy cargo against jarring.

No More Exploding Cows

SOMETHING unusual in aluminum safety equipment is the Christiansen safety valve for cows. A rather common complaint of cows is too great indulgence in alfalfa, with the result that the cow becomes badly bloated and in danger of death.

The standard treatment for this condition has been to ram a pitchfork into the cow's ribs, puncturing the stomach and allowing the accumulated gas to escape. Since this is rather hard on the cow, Dr. P. J. Christiansen developed an aluminum safety valve with glass check ball, which is permanently inserted in the cow's side. A cow which heasts this latest piece of spare equipment can est

Mechanical carrier for harvesting pineapples

its way through a field of alfalfa, and except for a slight whistle of gas through the valve, suffer no ill effects.

The aluminum valve is light in weight and is not easily corroded by the weather and the escaping gas.

PINEAPPLE HARVESTERS

SE of 30 mechanical field fruit carriers during the 1938 harvesting season on the Hawaiian pineapple plantations of the Hawaiian Pineapple Company, Ltd., has convinced both workers and management that they effectively eliminate the most onerous feature of pineapple plantation employment.

Prior to the use of the machines, plantation workers gathered the picked fruit along each row and carried it in bags on their backs to the end of the row where it was placed in boxes to be loaded onto trucks. The mechanical carrier, moving under its own power, is now accompanied down the row by two loaders who need merely lift the previously picked pineapples from the tops of the plants and place them in one of the machine's two hoppers.

From the hoppers the fruit is fed auto-

crown of each pineapple is cut off by a buzz saw. The elevators raise the pineapples to conveyors which carry them to the boxers. two of whom-one for each conveyor-stand with their supply of boxes between the conveyors, on the machine. At the end of the row the filled boxes are transferred directly from the carrier to motor trucks.

Motive power for the carriers is supplied by a Ford "60" motor, giving them a top speed of 10 miles an hour. The elevators and conveyors are powered from a separate two-horsepower engine

ACCURATE PICTURE RECORDS OF SALESMEN'S SAMPLES

MANY a business argument over substi-tutions or incorrectly filled orders can be avoided through use of a new Kodak Sample Record Outfit. Clear, accurate, detailed pictures of a salesman's sample can be made in a moment with this inexpensive, readily portable outfit-even by one who has not the least knowledge of photography. Regular snapshot film is used. Eight pictures-showing different samples or differ-

matically onto two elevators where the

Photography makes possible accurate recording of submitted samples

ent views of the sar on a 25-cent roll of film, Any photo finisher can develop this film, and prints cost but a few cents each.

Thus, the Sample Record Outfit provides perfect means for completing store records—accurately, easily, inexpensivelyand avoiding disagreements, ill-feeling, and time-consuming, profit-consuming correspondence when delivered merchandise does not correspond with the sample from which it was ordered.

The buyer places the salesman's sample maide the record outfit, along with a card bearing the catalog number as stated. He then presses a light switch and touches a shutter button. It's as simple as that, and the result is a clear-cut, detailed picture of the sample actually shown. Nothing is left for argument or misunderstanding. The picture speaks for itself when compared with the delivered merchandise. And with this outfit. it's quicker to take a picture than to wait while a salesman writes out a long description.

Pictures taken with the Kodak Sample Record Outfit may be filed for use when reordering. More complete stock records may be kept, a picture of each article or style being attached to the proper inventory card. Any sample or object up to 61/2 inches high, 11% inches long, and 4% inches deep can be pictured.

FOOD

RAILWAY dining cars serve approximately 25 million meals a year, the equivalent to serving every inhabitant of a city of nearly 23,000 population with three meals a day for an entire year.

PUTTING "B. O." TO WORK

ODY odor is finding important industrial applications quite aside from its function as much advertised "B. O." in selling a particular brand of soap. Sebacic acid, important constituent of human sweat, is being synthesized and used in large quantities as an essential raw material in making softeners (plasticizers) for resin plastics and in making a new type of resin which yields a silklike fiber far superior to ordinary rayons. Caproic acid (normal hexoic acid), which bears a relation to the body odor of goats which is similar to that of sebacic acid to humans, is finding numerous important uses since its recent synthesis has made it an industrially available raw material.

No, the products made from these acids do not necessarily have the same odor. In fact, many of their industrially useful derivatives are odorless and still others actually possess pleasing fragrances.-D. H. K.

HANDS CAN CARRY DANGEROUS GERMS

OW clean are your hands? The "resident" flora of the same and hands of Dr. Philip B. Price of Johns Hopkins University School of Medicine, un ordinary conditions, is around \$1 micro-organisms. Some of those are germs. But, in addition to these

flore, Dr. Price and you and I have "transient" form. When the hands are dirty, the transients are present in enormous numbers. The transients, however, are comparatively easy to remove or kill. Not so with the residents.

If the hands are in frequent contact with contaminated objects a dangerously large proportion of the resident bacteria may be pathogens. In such cases it is almost impossible to disinfect the hands. In this hitherto unsuspected manner a person may become a carrier of virulent disease organisms, according to Dr. Price.

After the long, elaborate, and painstaking scrubbing and disinfecting that the surgeon gives his hands before an operation, he succeeds in reducing the number of bacteria to around 200,000. Then he puts on sterile rubber gloves.

Dr. Price has tested various disinfectants with a view to use in preparing the surgeon's hands for an operation. A minimum of seven minutes with soap, warm water, and a good brush is needed to remove the transient bacteria and fats, gross dirt and, incidentally, about half of the resident flora.

Dr. Price has tested all the germicides in their effect on the resident bacteria. Some he finds good, some useless .- Science Service.

PRESERVING FINISHED LUMBER

STAIN and decay which attack wood are not entirely avoided by painting. Consequently many toxic materials have been suggested for use in treating wood for its preservation before painting. The Western Pine Association has recently conducted careful comparative tests of some 43 such wood preservatives. As a result of these studies, four of the compounds tested have been shown to be effective. Of these, pentachlorophenol, tetrachlorophenol, and 2-chloro-ophenylphenol are recommended for commercial use on lumber. A fourth compound, ortho-phenylphenol is also effective but at present is too expensive for commercial use. When dissolved in specified petroleum solvents and applied to finished millwork, these materials confer a high resistance to stain and decay over many years without interfering with painting or otherwise causing trouble in the normal use of the lumber.—D. H.K.

COLD LIGHT (LUCITE) SURGICAL INSTRUMENTS

GROUP of surgical and dental instruments which concentrate light at any desired point, and piped illumination bringing a powerful, sterile beam of light into the operating room without heat or glare or danger of electrical shock, have been made possible by Lucite (methyl methacrylate), the crystal-clear and practically unbrestable plastic developed in the laboratories of du Pont. The faculty of this plastic, like quarts, of carrying light around curves, is primarily responsible for the ad-rantages of these instruments. Automy the energical instruments with

qualities not erroriously available is a tongue depicted, made from a curved Lucito rod, and from the control of the cade of t

Two uses of piped cold light. Left: In dental work. Right: Transillumination of a sinus. Note the illuminated area visible just over the right eye of the patient

single instrument, the operator's hands are left more free, and the examination is simplified. The source of the light is a small electric bulb at the base of the plastic depressor, which receives its current either from a cord, transforming 110 volts to six volts, or from a flashlight base made for this especial purpose.

The tongue depressor gives a white and brilliant light, showing up the tissues in their truest color, because "Lucite" partially filters out the infra-red rays. Moreover, the light is cold, because Lucite is a nonconductor of heat-a comfort factor for the patient; and is shadowless because concentrated at the exact point desired. A laryngeal probe, designed principally for deep throat work, and useful in both diagnostic and operative procedures, is another dual-rôle instrument, combining light and probe in

The double function and improved light ing qualities are also found in a group of retractors. These instruments are used to hold back the tissues while operating, affording the surgeon a clearer view and better access to the field of operation. In these new illuminated retractors, here again there is the advantage that the curved shape and the accurate focusing of the light rays give better illumination to the field of operation. Also the elimination of heat, for certain retractor uses, is important to the patient's comfort.

Transilluminators for various specific purposes, intended for diagnostic work-for example, the sinuses—are included in this series of instruments made by the Curvlite Sales Company.

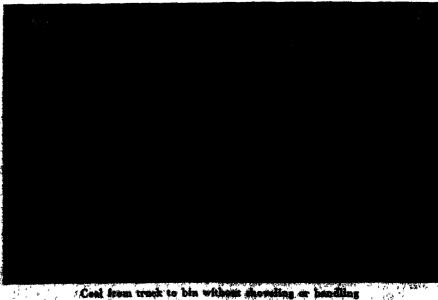

POWER

THE combined output of the first three generators now under construction for Grand Coulee Dam will equal 324,000,000 watts-enough electricity to light approximately 5,500,000 60-watt house lamps, or supply illumination to New York City and Chicago combined.

TRUCKVEYOR

NEW coal truck device which offers a clean, quick, and economical way to deliver coal by eliminating wheeling and shoveling and by reducing delivery costs, has been anounced by Gar Wood Industries,

The truckveyor, as this device is called, makes it possible for a truck to do the same work as a high-lift or double-elevating unit, such as chuting coal over long distances, into elevated bins and over terraces, and at the same time reducing the over-all height

Coal from truck to bin without shouling or h

of the body as compared to a high-lift, eliminating excess weight, and permitting more pay load to be carried at considerably lower cost on the same size truck.

The truckveyor does not interfere with the use of the truck as an ordinary dump unit, when required, and it is not limited to coal deliveries, but may be used for other commodities as well.

The truckveyor consists of a strong, aluminum-alloy frame supporting a heavy-duty eight-inch rubber belt on two four inch aluminum pullevs, one at each end of the truckveyor. The drive pulley has a right-and left-hand gear box operated by a flexible shaft which is connected to the truck power take-off by means of an auxiliary shaft and universal joints. Hinged baffle plates and extension sides on the conveyor frame are provided to prevent spillage. When not in use, the truckveyor is carried in a compart ment built inside the body, or held on the outside by retaining brackets.

ACID PLANTS USE RARE METAL

MANTALUM, a relatively rate and expen-L sive metal, is effecting important economies in the manufacture of hydrochloric acid. Because the metal transmits heat readily and much heat is generated when hydrochloric acid gas is absorbed by water, absorbers huilt of tantalum are almost midgets compared with stoneware and fused silica plants which have previously been the rule. Tantalum is one of the very few metals which will resist the attack of hot hydrochloric acid, and, despite its high cost, plants built of it are more economical than old style plants. A single absorbing column six inches in diameter and a little over six feet long has a capacity of 3000 pounds of 20degree acid per hour.

This and other developments in the use of tantalum are encouraging the Belgians to develop rich deposits of its ores in Belgium's tropical African colonies.—D. H. K.

VOICE-POWERED PORTABLE TELEPHONE

A PORTABLE telephone which gets its power solely from the speaker's voice and requires no external source of power

Inside the batteryless phone

was announced recently by the Western Electric Company. A measure of the new instrument's effectiveness is gained from the fact that it will, with an efficient telephone line, transmit speech over distances in excess of 200 miles.

The "magnetic" telephone, as the device

is known, was designed by Bell Telephone Laboratories primarily for use in such places as railroad yards, ships, coal mines, construction camps and similar locations where the need exists for simple, highly reliable, and portable communication facilities.

In size and shape the instrument resembles a child's building block and its secret of operation rests in a small, though power-

Voice-powered telephone that requires no battery. Hand crank is used only for calling the other party

ful, magnet. "Voice currents" are generated when the flux from this magnet is influenced by the motions of a metal diaphragm assembly vibrating under the impact of sound waves. An identical instrument at the receiving end acts in reverse order to reconvert the voice currents into intelligible speech counds. Each telephone is fitted with a small hand crank for generating a signalling tone. The "called party" hears a shrill, distinctive note, similar to that emitted by a fire siren, which is especially capable of penetrating through noise.

Protection against weather and mechanical injury is provided by a semi-hard rubber housing, and convenient connection with the telephone line, a matter of a few seconds, is made by means of a waterproof cord, the conductors of which terminate in spring clips.

PLANES

AMERICA'S aviation industry could triple its present production rate of 320 planes a month without greatly expanding its factory facilities. According to a Science Service writer, there is only one potential brake: the need for a far greater number of highly skilled tool makers than are now employed in the industry and who would require time for training.

A NEW MOLD MATERIAL

CIENTISTS working with limestone, coke, and salt scored a victory over nature in the development of Koroseal, a synthetic product possessing rubber-like properties. After being tested for over four years, Korogel, a soft variety of Koroseal, is now being recommended and used as a mold material for casting plaster of Paris, cement and concrete, artificial marble, and almost any kind of synthetic stone.

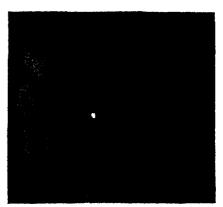

Korogel is not affected by water or the common materials found in casting shops. Molds made from it do not require any sizing or other treatments between casts. It is not affected by atmospheric conditions so

that the same composition may be used in winter and in summer. It does not dry out or deteriorate with age, allowing molds to be stored for indefinite periods of time and still he usable. Korogel does not shrink, expand, or distort in service. If handled with reasonable care, over a thousand casts may be taken from the same mold. Unlike rubber products which have been proposed for similar service, Korogel can be remelted and used over and over again.

Small lots of Korogel can be melted readily in an ordinary enameled household double boiler, using in the outer container a high boiling oil as the heating bath, and heating over a gas burner. Larger lots can be melted by adapting the double boiler principle to equipment of the required size or by using electric heaters especially designed for the job.

Having melted the material, it is allowed to stand without stirring or additional heating until it has cooled to the point where it will just flow freely. The model over which the mold is to be made is arranged in the usual manner with all high points of the shell or retainer fully vented. Obviously, for objects such as plaques and other simple pieces an open-back mold is satisfactory and a shell is optional. The Korogel is poured slowly until the space allotted is filled. After pouring, the mold is allowed to stand until cold. At such time the model is removed and the mold is ready for use.

Good Korogel molds can be obtained from models of wood, metal, glass, ordinary plas-

Molds of Korogel are pliable, can be removed from casting undercute

ter of Paris, Hydrocal, metal casting plaster, Keene's cement, and almost any other rigid material which is not affected by temperatures of approximately 275 degrees, Fahrenheit.

A great deal of publicity has not been given Korogel thus far, the manufacturers and distributors preferring to carry on a conservative testing program with a few users. Adaptability to the service together with low operating costs is resulting in increased demands for the product.—S. L. Brous, B. F. Goodrich Company.

COLORED LIGHT FOR MOTOR CAR HEADLIGHTS

ANY thousands of motorists use headlights giving a colored light in the belief that they possess advantages over white light of the same power for driving at night or in fog. It is claimed that with colored light, objects on the road are more easily seen, that glare is reduced, and that the colored rays penetrate farther into mist or fog.

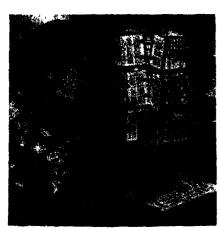

Legislation in France compelling the use of headlights emitting yellow light has served to focus attention on this problem, investigation of which was undertaken by the British Medical Association. The Association reported that extravagant claims had been made for yellow headlights, and that no definite recommendations could be made in any direction.

It is emphasized that, in deciding upon the relative merits of white light and colored light, it is of great importance to note that when colored glass is put in front of a lamp it not only colors the light, but also reduces its brightness. False conclusions are often drawn through failure to separate the effects of change of color from reduction of brightness.

None of the claims made in favor of using a colored headlight beam, yellow in particular, rather than a white beam of the same power, has been substantiated. The claim for a greater range of visibility in fog may be regarded as definitely disproved. As for the other claims of less glare and greater facility of vision, the evidence is inconclusive, but it is apparent from the information at present available that no considerable advantage can be secured by using colored light.

ROTATING RECORD SYSTEMS

TWO new and economical record systems that promise to make the office a new source of profits through savings in low cost of housing, increased volume of work per

Revolving card index wheel that shows the entire face of any card

operator and decreased amount of floor space required, have just been announced by the Diebold Safe & Lock Company.

Years of laboratory and field research, including careful analysis and study of test installations under all kinds of operating conditions, brought to light the following as the desirable objectives for card filing systems: Systems should bring the cards to one common position for reading or posting; The entire face of each card should be in readable position; Both sides of the card should be position; Both sides of the card should be quickly available; All reference and posting work should be done at one position—desk begin; All reaching and stretching motions should be diminated in order to avoid undily latigating the operator.

Both Cardineer and Reveldex Filing Systems have been designed to afford these every-day working advantages. They have made practical the application of rotation to record systems—rotation that brings every card to one common reading and writing position.

The Cardineer is a molded plastic wheel, housed in either a metal cabinet or supported

Another type of index wheel that greatly simplifies clerical card work

on a stand. It is available in different diameters for housing from 1500 to 6000 cards and will take care of cards five, six, and eight inches wide. The cards are threaded on metal bars through slotted holes punched in the bottom of the cards, the bars being attached to the wheel by means of a patented locking device. For check or stamp posting, the cards need not be removed from the wheel If they are to be posted by hand or machine, they are readily removed from the wheel with one hand, posted and returned with little effort.

Reveldex wheels revolve in a horizontal plane instead of the vertical plane in which the Cardineer wheel revolves. Reveldex cards are held at two points instead of one and are intended as reference records whereas Cardineer may be used for both reference and posting records.

FERTILIZER SAVES BEETS

CROWERS of sugar beets and refiners of sugar from them have suffered heavy losses from rotting of the vegetables in storage piles. Recent experiments have shown that fertilizing growing beets with phosphates not only increases yield but at the same time makes them substantially more resistant to rotting. Beets grown on soil deficient in phosphate are reported to rot three to five times as fast as those properly fertilized.—D. H. K.

MAN NO NEWCOMER IN AMERICA

BELIEF that primitive man lived in Florida at the close of the Ice Age, from 10,000 to 15,000 years ago, hunting the mastodon, elephant and saher-toothed tiger, has received fresh confirmation from investigations conducted by Dr. H. G. Richards of the New Jersey State Museum.

In a report made public by the Geological Society of America, Dr. Richards states that he revisited the site of Vero Beach on the eastern shore of Florida, where parts of three human skeletons, associated with bones of animals, including many extinct species, as well as hunting implements of flint and hone, were discovered in the bank of a drainage canal more than 20 years ago. Among anthropologists these finds have been the subject of years of lively dispute

Since the human remains were found only a few feet below the surface some geologists suggest that they represent a hurial that took place relatively late in geologic time. Others, arguing from the undisturbed condition of the layers of rock above, and from chemical analyses of the human and animal remains which revealed similar changes in mineral content, maintain that the human remains were contemporaneous with the remains of extinct animals which are known to be of Pleistocene age.

Pleistocene age.

Dr. Richards's findings support the latter view. He examined the layers of sand and sandstone in which the remains were found, as well as the overlying and underlying beds of shell, marl, muck, and limestone. The older or underlying beds, he states, were laid down in periods when the Ice Age glaciers receded temporarily from northern latitudes, melting and feeding the seas, which then grew in depth and covered the coastal plain of Florida.

Dr. Richards found that, during the Ice Age, Florida's climate fluctuated much as did the climates in more northern latitudes. When ice sheets receded in the north, the climate was at least as warm as that of today, and when they advanced the climate was much cooler.

Stainless-steel cooking utensils that are good-looking enough to be used on the table are a new labor-saving device for the housewife. The one shown is a baking dish that came direct from the oven to the table

STARCH FROM SWEET POTATOES

MANUFACTURE of high grade starch from sweet potatoes grown on cut-over pine land in the South has proved commercially successful on a scale of production of 15 tons per day. The project seems to offer promise in the agricultural rehabilitation of the southern states by providing a prolific crop with a ready sale to supplement cotton and tobacco as cash crops.

Yields as high as 500-600 bushels per acre have been realized in experimental plantings of selected varieties of sweet potatoes in southern Mississippi where this industry has been started. Average yields from many plantings over a period of several years have run as high as 300 bushels per acre. These compare with a general average yield of sweet potatoes of 78 bushels per acre in the

United States. Selection of variety of plants and care of the crop account for the difference.

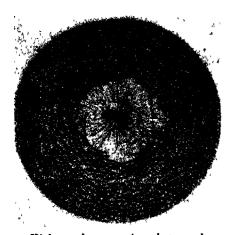

The starch manufacturing process is similar to that used in Europe and in Maine employing white potatoes as raw material but is modified to meet conditions. [See also page 280, May, 1938, Scientific American.—
Editor.]

Development of the agricultural aspects of the sweet potato crop—it has not heretofore been a large-scale farm product—is being pushed to make it fully profitable to the grower since the feasibility of the project has been demonstrated—D H K

How Fast Does Glass Break?

WHEN glass breaks the cracks move at the amazing speed of nearly a mile a second or more than 3000 miles an hour. The speed of cracks, knowledge of which may lead to stronger and safer glass, was accurately timed by high-speed photographic research at the Massachusetts Institute of Technology.

The accompanying stop-motion photograph, made at an exposure of less than one-millionth of a second by Graduate Student Frederick E. Barstow and Professor Harold E. Edgerton, shows cracks radiating from the center of a piece of tempered glass and the formation of lateral cracks at the instant it was struck by a metal plunger, the dark spot at the center of the picture. Observe

High-speed stop-motion photograph that shows how cracks form in glass

that the pattern of the cracks forms a perfect circle, visual proof that all cracks grow at the same velocity. Radial cracks appear to move outward, while lateral fractures seem to move inward.

PHEASANT-CHICKEN Hybrid

AFTER five years of experiment, the members of the Science Department of Avon Old Farms, a college preparatory school at Avon, Connecticut, have finally succeeded in crossing a pheasant cock and a game hen. So far as is known, this is the first time this has been done. The boys found that the secret lies in mating the birds in the fall rather than in the spring.

The hybrid shows many chicken and pheasant characteristics. Both sexes seem to possess the red eye ring of the male pheasant. A ring is present around the neck of the birds similar to that of the Ringneck male but black in color instead of white. Plumage is markedly chicken in banding and color.

The boys who successfully conducted this experiment are 12 to 14 years old and are members of the first two forms of the school.

Newly developed, Hastolite Bakelite resin coating for metals protected one side of this panel during a two-year test exposure to gasoline, hot salt water, and moist air. The coating still retains its gloss. Picture at

right shows that the unprotected surface of the same test panel is severely corroded

HYDROGENATED ROSIN

COMMON pine rosin, which contains the cheapest organic acid and whose industrial usefulness has been limited by its tendency to oxidize and discolor in use, has emerged from the process of hydrogenation as a virtually rejuvenated raw material. Treatment with hydrogen in the presence of a suitable catalyst improves the color of low-grade rosin until it is whiter than even the highest present grades. At the same time a change in the character of the rosin is produced which prevents it from discoloring in sunlight. This process, which is covered by patents, is expected to enlarge the usefulness of rosin materially.—D. H. K.

V-8 Engines Get Novel Task

MONG the more unusual tasks performed by automobile engines should be listed that of four V-8s in the Ford Motor Company's new tire plant. The engines are operated for the exhaust gas they produce, and the power they make in the process is utilized to compress the gas.

While at first glance this arrangement might seem to be an example of industrial bootstrap lifting, it actually is the solution of a problem found in "curing" tires.

The curing process is one in which the tire, with a heavy rubber tube or curing bag inside, is placed in a mold and subjected to heat and pressure. This forms the tread and makes the tire tough and durable. As formerly done, steam was first shot into the curing bag under high pressure, then it was drawn off and replaced by compressed air. The method was entirely successful, but there was one drawback: because of the

great heat and pressure the organ in the air caused the rubber curing bags to deteriorate too rapidly.

Tire engineers decided that using an inert gas, one containing no oxygen, instead of compressed air, would solve this problem. However, to buy enough inert gas for a busy tire plant would be expensive, and so they worked out the plan to make the gas with Ford V-8 engines, with the engines at the same time driving compressors to put the gas under the high pressure required.

Running at a fixed speed, the four V-8 engines on the job produce about 14,500 cubic feet of exhaust gas an hour, which is precisely the amount the four compressors are able to handle. The exhaust gas is piped from the engines through a series of cleaning and filtering devices, and then goes into the compressors as harmless carbon dioxide and nitrogen. The compressors raise the pressure to 450 pounds per square inch, and send the gas on to the curing molds.

ULTRA-SHORT RADIO WAVES BEND

THE dream of using ultra-short radio waves as secret signalling means during wartime is receiving little encouragement from experiments undertaken at California Institute of Technology, indicating that such waves—believed at first to travel solely in line-of-sight fashion—really can bend around the surface of the earth.

Prof. G. W. Potapenko and Dr. Paul S. Epstein of the Institute have recently completed preliminary studies showing that waves of five meters and one meter length can be picked up at a distance of 18 miles at sea.—Science Service.

MILK BOTTLE HOOD

A NEW milk bottle hood that combines a pure aluminum hand-seal and water-proof transparent window has recently been introduced in the dairy industry by Reynolds Metals Company.

The new "windoscal" is a pre-formed metal cap that completely covers the top and clamps under the lip of the milk bottle. The transparent window permits visibility of the regular printed paper plug.

Advantages of the new metal hood include: Elimination of stock of printed, predated hoods; elimination of preparatory and printing costs; and elimination of printing and embossing wearing away under icing

Why Do So Many Presidents

Enroll with the

ALEXANDER HAMILTON INSTITUTE?

MORE than 50,000 presidents and owners of American business concerns have enrolled with the Institute for executive training.

Why?

Because they know that organized knowledge of business is an essential

qualification to every responsible executive.

Because they know that modern business is too big to learn by personal experience alone.

Because they know that the Institute has gathered the experience of the most successful business men of America and the proved principles and methods of thousands of companies; formulated and organized this knowledge for their use.

Because they know that modern business has set new standards of executive competence and that the Institute training prepares them to meet these standards.

To Executives and Coming Executives The Institute Offers

ORGANIZED KNOWLEDGE of BUSINESS

The Institute training is not for Presidents alone—but it is planned only for executives and those who are determined to become executives. The Institute offers the knowledge and training without which no man is

qualified for executive responsibility.

For more than a quartercentury the Institute has been preparing men for business management, giving them the thorough, organized knowledge of production, marketing, finance, and accounting essential to

competent administration. Many of those enrolled have been ranking executives who recognized their need for better equipment; many others have been far-sighted men, twenty-five years of age and upward, preparing in advance for the opportunities they know will come.

If you belong in either of these two groups the Institute offers you the ideas, experience, methods, and judgment of the most successful business men of America, formulated and organized to give you a confident mastery of tested, modern business principles and practice.

If you are determined to command a higher place in American business life, to qualify fully for executive responsibility, to win for yourself financial independence, then you will want to read "Forging Ahead in Business" with its important message to men who want to go far in business. A new edition of this famous book is ready and we will gladly send you a copy free. Just mail the coupon.

Among the many American business leaders who have helped to build the institute's Course and Service are:

C. M. Chester, Chairman, General Foods Corp.; Thomas J. Watson, President, International Business Machines Corp.; Alfred P. Sloan, Jr., Chairman, General Business Machines Corp.; Alfred P. Sloan, Jr., Chairman, General Business Company of North Superiors Empleacies W. Pickard, Vice-President, Insurance Company of North Superiors, Reduction Resident, Air-Conditioning Division American Resistant Corporation; Robert H. Montgomery, Lybrand, Ross Chairman, Ross Managemery; John G. Lonsdale, President, Mercantile-Communical Business Co. Clifton Shusser, Vice-President, Goodyear Tire W. Regions, Chairman, Board of Directors, Assessed Business Company and many more.

conditions. The metal hoods are furnished in silver, gold, copper, and standard colors to distinguish between grades of milk or between competitive dairies.

SIGHT

THE fact that 23 percent of United States citizens have poor eye-sight before they reach 20, and 48 percent before 40, as recorded by the Illuminating Engineering So-ciety and American Institute of Architects recently, indicates the need for better schoolroom lighting.

NATURAL GAS STORAGE

THE storage of surplus natural gas in depleted gas sands during periods of low consumption is an important conservation measure, and a boon to distributing companies. Most of these companies procure their gas both from natural gas reservoirs and by purchase of gas that is a by-product of oil production and natural gasoline extraction. Due to the use of natural gas for heating, the greatest demand for it is during the winter, while the greatest supply of the by-product is available during the summer, frequently at a relatively low cost. Stored at low cost in underground reservoirs favorably located with relation to large markets, it reduces the load on long transmission line systems during periods of peak demand and may obviate the need for heavy investment in new pipe lines.

Practically 100 percent of the gas stored in an exhausted field may be recovered if the field is protected against offset drilling, if the formation is impervious to leakage, and if the old wells are tightly sealed.

Early in 1936, Oklahoma Natural Gas Company examined a small field in Tulea County from which most of the gas had been exhausted. The original rock pressure in this pool had been 560 pounds per square inch. Several paying wells had been drilled and approximately 500,000 cubic feet of gas had been removed from the field before the pressure had declined to about 100 pounds per square inch. A series of dry holes showed that the pool was geologically closed and defined the limits of the pool which covered an area of nearly 160 acres.

In order that the entire area occupied by this reservoir might be covered by contract, the Company secured storage rights upon approximately 360 acres. In addition, a regular five-year commercial oil and gas lease was executed. The gas remaining in the reservoir that could be removed if the pressure were reduced to 50 pounds per square inch was calculated and the owners reimbursed. After the necessary rights had been acquired, all the abandoned wells were checked for proper plugging, and two wells were left for the purpose of introducing and later extracting gas. During the summer of 1937, gas which could be bought at a low price from gasoline extraction plants was injected into the depleted sands with the aid of a compressor. The reservoir was alled rather slowly in order that electrations of the resulting pressure could be carefully noted. Approximately 77,000,000 cubic feet of gas was injected into the reservoir and the preseure increased to 232 pounds per

square inch. Starting some two months later, during the winter months, withdrawals were made in accordance with market demands in Tulsa. By the end of the winter nearly 79,623,000 cubic feet had been withdrawn, about 2,500,000 cubic feet in excess of input, and the pressure of the reservoir still was 50 pounds per square inch above the pressure at the time the injection of gas was begun. The reason for this increase in pressure is not known exactly, but it may be due to eheroschment of water in the reservoir space sometime after starting the injection of gas.

Due to the fact that a relatively small amount of equipment was necessary to handle the gas, and no great expense was involved in securing the storage rights and placing the wells in condition, the total cost per 1000 cubic feet for storing and extracting this gas was below the standard field price in this area .- Stone & Webster Bulle-

RADIO TROUBLE-SHOOTER

ELECTRICAL communication has become a vital part of modern livingon sea and land, in business and in the home The transmitting and receiving apparatus has reached a high state of development, but since it is machinery, the fact is recognized that it might get out of order. Hence one of the major problems encountered in the communication field is to repair the break down when it occurs. Naturally, this must be done quickly and accurately

An entirely new method of diagnosing trouble in radio and television transmitters

Chanalyst

and receivers, public-address systems, and other devices in which vacuum tubes are used, has been made possible by the Rider Chanalyst. Heretofore, trouble-shooting methods have been based upon testing the static condition of individual components of the device, upon operating voltages, contimuity checks, and the like, but these methods were uncertain and time-consuming. With this new instrument, it is possible to determine how different circuits are functioning without disturbing the performance of the apparatus as a whole and when that portion of the unit is found in which the signal departs from normal, the cause of the trouble is sought in that particular location with such secondary tests as those mentioned above.

Essentially the Rider Chanalyst consists of radio-frequency and audio-frequency channels terminating in electron-ray indicator tubes, by means of which the signal itself can be traced and studied in its course through the apparatus and without disturbing the delicate balance of the several circuits. An ultra-sensitive electronic voltmeter provides a means for measuring accurately can be traced and studied in its course

Unquestionably, the leading home generator of ultraviolet light, this marvelous lamp should not be confused with cheaper imitations. The Hanovia Alpine Home Sun Lamp generates eleven powerful wavelengths covering the entire useful and beneficial range of ultraviolet light. It takes but a few minutes-after a snap of the switch—for a complete, invigorating, healthful ultraviolet sun bath Regular sun bathing under this lamp builds resistance against colds and common ailments, gives a ruddy outdoor appearance

all D.C. voltages up to 500 volts without interfering with the operation of the circuits by loading, as the input resistance of the meter is 10 megohms. For sural or visual inspection of the signal, provision is made for pluggingin head-phones or a cathode-ray oscillograph.

While the Chanalyst is especially adapted for test work, it readily lends itself to classroom and lecture demonstrations as a comparison receiver.

PLAYGROUNDS IN THE AIR FOR EVERYONE!

THE "City of Tomorrow," recently displayed in New York, proposed that sidewalks of the future be covered with "bouncing," resilient materials to reduce walking fatigue and to deaden the noise of millions of moving feet

This idea is by no means new. Shockabsorbing surfaces for outside walking and other activities-decks, walks. and roofshave long been sought. It has been realized that the development of a suitable resilient material would permit the wholesale con version of acres of flat city roofs into recreational areas, open to the sun and safe from traffic in the streets below

The recent development by engineers of The Celotex Corporation of a resilient wearing surface for exterior use is aimed at this problem After a long series of tests, the material has now come into practical use under the appropriate name of "Promenade Traffic Top.

Traffic Top is a bagasse fiber board impregnated with selected bitumens by a special process. This board, left naturally black, or coated with an elastic color finish, may be bonded to any rigid base, it is claimed When used as a roof surfacing, it may be applied directly upon the built-up membrane of the roof. When used on a walk or ramp. its manufacturers recommend that it be cemented directly to the concrete, wood, or composition base. The cement used should be either a hot brushed-on asphalt, or a cold asphalt adhesive that has been prepared expressly for this purpose by the makers of the board.

Good traction is claimed for the board, even when wet. For this reason, it is recommended as a promenade surface around swimming pools, or wherever there is a continually wet condition. All exposed surfaces subject to foot or light wheeled traffic may be covered with it. A concrete tennis court, for example, when covered with green Traffic Top, has much the "give' and the color of a real lawn court.

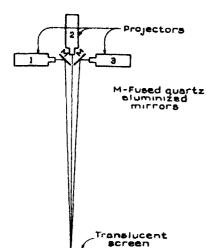

Playgrounds, roof tops, courts, and pedestrian approaches in schools, hospitals, apartments, office buildings, hotels, and residences may be advantageously covered with it. It makes an ideal surface for residential play roofs, since it will reduce transmission of noise of moving feet to the rooms below. It is light in weight-lighter, in fact, than a conventional slag roof-and requires no extra supporting construction.

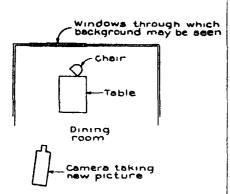

FUSED QUARTZ SOLVES COLOR MOVIE PROBLEM

LEAR fused quartz, a product of General Electric's Thomson research laboratory at Lynn, Massachusetts, has been given an exceptional assignment in the mo-

tion picture industry. It has solved a problem that arose with natural-color pictures and, as a result, a feature movie, soon to be shown, will have a scene depicting an old southern gentleman arguing with his negro servant about some pork chops, while through the dining room windows can be seen several thoroughbred horses grazing peacefully in a beautiful green Kentucky meadow.

The dining room in question is on a Los Angeles motion picture stage. Outside

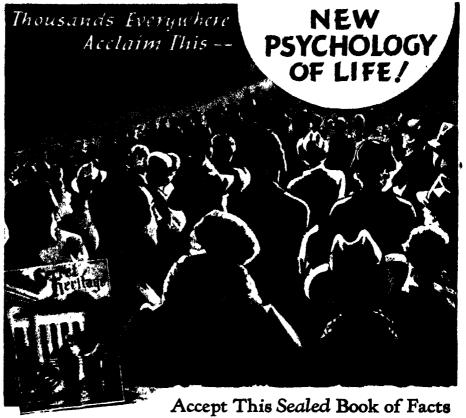

How three projectors were used recently to produce a "composite" shot in a new color motion picture

the windows is a translucent screen called a "transparent" by the film folk. The meadow and horses are projected on this screen from the back, with a motion picture projector, and appear as natural as nature from the front side through the dining room windows.

In the days of "black and white" pictures this was simple. The camera taking the new picture and the machine projecting the background were driven by synchronized selsyn motors so that no flicker could be seen on the background in the new picture.

Then came color, and the technique was changed overnight. The amount of light required to take a picture in natural colors was two or more times greater than that required for black and white. It simply was not possible to get enough light from one projection machine for the average size background in color and in motion.

As a matter of fact, three projectors are required, and they must operate in exact synchronism, and in synchronism with the camera taking the new picture. This part was easy, for selsyn motors took care of that. But to make the projected image clear and that, the three cameras must project from

Have you unrealized hopes? Are the better things of life always just beyond your reach?

Times have changed – but have you? Do you still believe that some were born to have eventful lives – to have fame, fortune, and power, and still others destined to be mere plodders? Are you able to demonstrate a change in your affairs, to put your circumstances in order, and move forward to a better station in life? If not, it is time that you adopt a new psychology of life and learn to MASTER YOUR PROBLEMS.

It takes no greater mental effort to achieve results—when you know how. Successful living is the oldest art in the world. It consists of developing initiative, foresight, and the ability to combine experiences into new and workable ideas. The knowledge of this art was acquired in centuries past through the personal sacrifices of the ancient sages, who dared to investigate life's mysteries. Their discoveries of the secret functionings of man's mind have been preserved by the Rosicrucians, an age-old, world-wide fraternity (not a religious organization).

The Rosicrucians Offer To You

—if you have the courage to break away from limited forms of thinking, these same simply expressed truths of life, which have led thousands to a joyous method of better living. If you are sincere—use the coupon below and secure the fascinating /ree book, "The Secret Heritage," which tells how you may receive this knowledge.

very nearly the same point, much nearer the same point than their physical size would permit.

This was solved by having one camera shoot directly at the screen from a point directly away from its center. The other two project against mirrors set at 45-degree angles. This may be understood clearly by referring to the sketch. The mirrors are so placed that, standing directly in front of one of the projectors and looking into its lens, the lenses of the three projectors appear to be equally spaced about an imaginary circle whose diameter is scarcely greater than the diameter of one of the lenses.

Because of the intense heat, ordinary silvered glass mirrors could not be used, so General Electric supplied aluminized fused quartz plates, accurately ground to $\frac{1}{2}$ wave length. The silvered glass reflectors first tried required refinishing after a few hours of use, the fused quartz mirrors have operated month after month with complete satisfaction

New Element (?)

CERMAN research workers report a hitherto unknown product of radioactive transformation which may be a new element. The properties of the material suggest that it is eka-tridium with an atomic number of 95 Previously it has been generally agreed among chemists that there could not reason ably be more than 92 elements and that there was no use searching for others since all 92 are known Perhaps, as this suggests, there are new elements yet to be found —D H K

IF YOU FIND A METEORITE

THERL may be "stones from Heaven" in your doorvard. If so, the Smithsonian Institution, at Weshington, D. C., would like to add them to its collection. Scores of supposed meteorites are sent to the Smithsonian experts for identification. Usually they are almost exactly the opposite of what a meteor really is, due to a popular misconception of what such an object should be Folks see a shooting star—a blaze of fire in the sky. They assume from this that the stone itself should be burned to a crisp when it luts the earth As a result the most frequent specimen sent in for identification is a chunk of slag from some furnace.

Actually, if you pick up a stone that seems exceptionally heavy for its size, it is well to make inquiries. Meteorites are about the heaviest of rocks, Some of them are pure iron and nickel Even in an iron manufacturing district, lumps of pure iron are very rare, and if you find one anywhere else the chances are greatly in favor of its origin in outer space

Even the so-called "stony meteorites" contain a good deal of iron and are heavy enough, compared with ordinary stones, to arouse suspicion. A good way to get corroborative evidence is to take such a stone to the grindstone and grind away a small bit of surface. If you find the area thus exposed speckled with iron particles, the chances are rather good that you have a meteorite. Do not injure the exterior surface too much, as it is of interest to the students of meteorites.

The discovery of a meteor is always worth while to the finder, although the value is not

so great as is often believed, but it will bring a very good return for a day's work.

It is sometimes wondered why a meteorite can strike the earth without setting everything on fire if it lands in combustible material. Strangely enough such an object might not be too warm to hold in the hands It entered the earth's atmosphere far colder than anything on earth could possibly get except in a special laboratory. It made its whole journey to earth in a few seconds Only an extremely thin layer on the outer surface was heated and this heat did not have time to penetrate the interior. So, if you should happen to see one of these balls of fire strike the earth rush to it and see how warm it really is. There is only a slight chance that it will be hot enough to burn your fingers. There is at least an equal chance that the meteorite may be covered with frost

RUBBERFLEX PILLOW Block

IN answer to the widespread demand for a compact, sound insulated pillow block, SKF Industries, Inc. 15 introducing the Rubberflex pillow block This new unit comprises a self locking bearing of the wellknown SKF Grip-lock type. This bearing is inherently aligning, thus compensating for

maccuracies of set-up and conditions of shaft misalignment without binding or in any way impairing the load carrying capacity of the bearing. In addition, the use of this unit brings about manufacturing economies because it requires no machining of the shaft.

The bearing is encased in a pressed steel housing equipped with felt seals to exclude dirt. The housing is provided with means for lubricating the bearing. The bearing and housing are surrounded with an elastic material having special sound absorbing characteristics, and the material has been specially treated to make it impervious to oil and grease.

Free from the objectionable vibration usually associated with rubber mountings, this unit carries substantial loads under practically all operating conditions, Its construction facilitates mounting. The units are first being released in the "4" and 1" shaft sizes.

in

BIFOLIATE GEOMETRY

by Robert A Philip

Price two dollars

THE MONOGRAPHIC PRESS 106 Washington St., Fairhaven, Mass,

lionths of an inch thick has a straw-yellow color, while a streak nine millionths of an inch thick appears red The colored areas thus constitute an accurate contour map of the "topography" of the oil film, the scale of contour levels from one color to the next being one or two millionths of an inch.

The colors reflected by transparent films having thicknesses less than five 100,000ths of an inch, called interference colors, have been understood since the days of Isaac Newton. However, until 1934 no method was known of building standard films of known thickness which could be used as color gages for measuring films of unknown thickness.

A method which was devised in the Gen-

A method which was devised in the General Electric Research Laboratory employs sheets of barium stearate which have a unform thickness of one 10,000,000th of an inch. Each sheet consists of a single layer of molecules of barium stearate. The layer is prepared by placing a small amount of stearic acid on water containing a barium salt. The individual molecules of which the stearic acid is composed endeavor to attach themselves to the water surface, with the result that the stearic acid spreads out over the water until each molecule has a place on the surface. The molecular layers are transferred to a metal surface by a dipping process at a rate of about 20 layers per minute.

Color gages are made by building on a polished chromium plate a series of steps having 21, 41, 61, 81, and up to 201 layers of barium stearase. These steps have thicknesses of two, four, six, eight millionths of an inch, which is the range of thickness in which films reflect most vivid interference colors. Films of other substances such as iron oxides, showing interference colors, are measured by comparing the color of the oxide with the colors of the steps of the gage.

In certain ranges of the color series, the eve can easily detect differences of thickness of one 10,000,000th of an inch. By means of suitable optical apparatus, differences of one 100,000,000th of an inch are measured. This means that single molecular layers of many substances which are of utmost interest to the biologist, chemist, or physicist can be measured quantitatively by the color change which a single layer causes when deposited on top of a barium-stearate film. Dr. Katharine Blodgett

to the skin, and feels neither hot nor cold. It can be easily shaped by dipping in boiling water, and then bending, and, consequently, can be re-used and re-shaped.

The Lucite plastic used is produced by the Plastics Department of E. I. du Pont de Nemours & Co., Inc. The splints were con-ceived by Dr. F. W. Probst.

MARKING INK FOR GLASS

THE problem of marking on glass or vitreous enameled surfaces has apparently been solved by a new type of marking ink recently perfected. The ink may be ap plied, with a steel or other pen or a marking brush, to the glass surface, preferably warmed, and when dry is resistant to all types of destructive agents, including strong acids and alkalies even when hot, and the common organic solvents. The ink itself is non-corrosive and non-flammable, in which respects it is more convenient than hydrofluoric acid marking fluids and organic substances -- D H K

SOLDERING ALUMINUM

LUMINUM is hard to solder because of A the oxide film that forms on it, according to The Foundry, which states that molten solder will not wet or alloy with aluminum covered with oxide. The most practical method, it says, is to abrade the surface of the aluminum under a film of molten solder so that the solder can wet the freshly exposed surface before it comes in contact with the air. When a small amount of solder has been melted on the surface, the solder is rubbed or worked with a wire brush. This abrades the surface, removes the oxide, and exposes a clean surface.

SIMPLE--WHEN YOU KNOW THE ANSWER

AFTER an amateur has given up finding fossils in a given locality, a professional paleontologist often will go to the same locality, walk directly to a definite spot and unearth fossils, much to the amateur's puzzlement. Accordingly, the amateur often asserts that the professional must smell the fossils, for there apparently is no other way by which he could locate them. There is, however: the professional knows many a

sign that the amateur never notices. And so it is with the archeologist, who seems to know where to look for buried human artifacts when there seemingly are no visible signs or clues. Again, however, it is often 'so simple" when the explanation has been given, For example:

Not only is vegetation more luxuriant over the sites of abandoned human villages in the Far North but it is composed of different varieties, says Dr. Ales Hrdlicka, Smith-sonian Institution Curator of Physical Anthropology, who for 12 years has conducted archeological explorations in Alaska and the Aleutian Islands. Some plants seem not only to follow the footsteps of man but to cling tenaciously to the remains of his settlements and to his graves.

"One of the main results of these explorations," says Dr. Hrdlicka in a recent report to Science, "has been the location of literally hundreds of more or less ancient sites. They cover from approximately one half to more than ten acres. They are kitchen middens and village sites combined, their accumula tions reach in depth from a few feet in some to more than 16 feet in others, and while some are fairly late others show human occupancy of many centuries

The appermost of their deposits reach from historic to pre-historic time. The accumulations consist of ashes, shells, sea urchin spines, rotted wood and sod, bones of fish, birds and various mammals, blown silt, and all the organic refuse and cultural objects of such communities. In their constituents, depth, and other conditions, they are largely different from the soil of the surrounding country

"Owing to these factors, the sites present wide and in some cases seemingly almost absolute botanical differences from the rest of their region. With some experience it is possible to detect such an old village site as far as it can be seen with some clearness. Its vegetation is darker and much richer in development. It sometimes reaches to over four, five, and in some cases six feet in height. At close range, moreover, it is seen to consist materially of different species of plant from those of the neighborhood. Some of these plants apparently exist nowhere else in the region, while not a few of those in the vicinity, in turn, do not grow on the site of the human habitation

"Apparently under different physical and chemical conditions in the ground the same region may produce very different and richer flora than is characteristic of the region un-der ordinary conditions"

CURRENT BULLETIN BRIEFS

SCIENTIFIC AMERICAN 24 W. 40th St., New York City, N.Y. Microscopic Detective Work" are only two of the six highly informative chapters. Leisure League of America, 30 Rockefeller Plaza, New York City.—35 cents.

THE OBSERVER'S HANDBOOK contains planetary and lunar data for each month of 1939, also star charts and numerous tables and summaries having practical value to amateur astronomers, very many of whom obtain the booklet each year from The Royal Astronomical Society of Canada, 198 College Street, Toronto, Ontario, Canada, for 25 cents

COLUMBIAN COLLODAL CARBONS is a 194-page book with semi-flexible covers, which deals with the industrial uses of colloidal carbon in the manufacture of rubber, inks and paints, and various other compositions. Attractively illustrated and complete in every respect. Binney & Smith 60, 41 East 42 Street, New York City -\$150

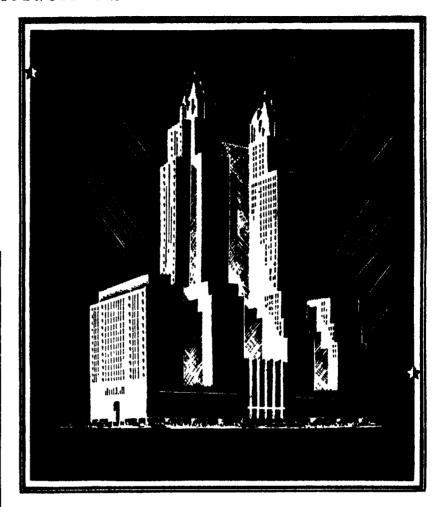

EQUIPMENT CATALOGUE, designed especially for radio "hams," service men, and sound equipment men, comprises 44 pages and has been compiled by an old time "ham" who is as familiar with quality requirements as are the users of the equipment listed. Sears, Roebuck and Co, Chicago, Illinois—Gratis

Modern Enlarging Technique, by Hanns Neumann, is a beautifully illustrated 54-page book that deals with the whole subject of photographic enlarging from "Why negatives are enlarged" straight through to "Mistakes, and how to recognise them." It covers enlargers in general, the darkroom and its equipment, negatives and enlarging papers, exposure, and all steps in the entire process. The numerous illustrations assist in an understanding of the comprehensive text. Burleigh Brooks, Inc., 127 West 42 Street, New York City —60 cents

SAFETY IN STEEL is a 20-page illustrated pamphlet that tells briefly the running story of industrial safety, particularly as applied to workers in steel plants. It deals with such things as protective clothing, safe operation of machinery, avoiding dangerous falls, and so on. American Iron and Steel Institute, 350 Fifth Avenue, New York City.—Gratis.

THE MERCURY SWITCH OF TOMORROW, Bulletin No. 500, is an eight-page pamphlet which describes Durakool Mercury Switches, which are now finding wide application in industry in general, "Few indeed are the switching jobs which cannot be done more safely, more surely, and in the long run more economically" with the switches described in this circular. Durakool, Inc., Elkhart, Indiana.—Gratis.

CREATIVE HANDICRAFTS, by Mabel Reagh Hutchins, is a 94-page hobby instruction book that will point the reader along the path toward making profitable use of spare time. It gives instructive and specific suggestions, accompanied by pertinent illustrations, in the following hobbics: pottery, weaving, basketry, metalcraft, leathercraft, bookbinding, block printing, and dyeing. Leisure League of America, 30 Rockefeller Plaza, New York City.—35 cents.

A Partnership of SCIENCE and ART

If there is such a thing as a hotel being the expression and the essence of the finer aspects of the life of a city, surely it is no immodesty to claim that distinction for The Waldorf-Astoria.

Here, not only the art of living luxuriously, but the science of living wisely and efficiently, and therefore economically, come to fruition in such a totality of advantages as only art and science together could achieve.

Science is the source of its creature comforts, but what most endears it to the world is its knowledge and its practice of The Art of Home!

Miroflex

(Former Model)

With Carl Zeiss Tessar f4.5 Lens 6"
Focus

THE Miroflex is an exquisitely built universal camera that combines the advantages of a sport camera with those of a reflex, enabling you to master every photographic problem indoors or outdoors.

Right up to the moment of exposure, the object can be viewed in the reflex mirror of this camera, and adjustments can be made up to the last second. The super-high speeds of the shutter (ranging from 1/3 to 1/2000 part of a second) are so fast that even the most rapidly moving object can be photographed with good results. The Miroflex can also be used as an ordinary camera on a tripod

It is fitted with bellows and when folded is compact and easy to carry. The hood jumps at the touch of a button, ready for instant action. The convenient eye-level finder permits an easy following of fast moving objects.

TRY CROPPING IT

OOKS are sometimes deceiving. If a nega-⊿ tive seems hopeless at first glance or even after some study, do not throw it into the discard without first giving it a chance to display its possibilities by projection on an easel under the enlarger Such negatives may sometimes be faulty because of poor judgment in taking the picture, unsuspected movement on the part of the subject which threw your carefully laid plan out of line, but which you shot just "on a chance," or other causes. But whatever the reason for doubting the print possibilities of a particular negative, do not trust first impressions Project it and see what can be done. There's always time for the waste basket

Take, for example, the illustrations shown here. Figure 1 shows a print from the full negative. We were making a number of flash shots when the mother suddenly lifted the

Figure 1: From the full negative

child into the air, as you see The camera was on a tripod and there was no time to do anything but shoot, come what may. The action was so spontaneous and graceful that picture appeal seemed inevitable. As it turned out when the negative finally came into being, the mother's head was quite close to the edge of the negative, and the chance of a suitable picture from even a part of the negative seemed hopeless for a while.

However, we put it into the negative holder anyway and, with the aid of the margin bands of the easel, made several attempts to frame portions of the negative. The results were decidedly surprising. The first attempt is shown in Figure 2, in which the vertical composition was tried. This did not appear fully attisfactory because the pose of the subjects gave the impression they were both headed straight out of the picture. Good balance seemed out of the question except by trying to cut down the portion of the negative used in making the picture. The projector hous-

Figure 2: Vertical composition

ing was raised to fill the easel picture space with a more limited portion of the negative.

The horizontal arrangement was the next experiment and the result, as shown in Figure 3, seemed to be an improvement. But we still were partial to the vertical arrangement and raised the enlarger housing still higher to make the finally satisfactory picture shown in Figure 4. In the last it was felt that the body of the woman provided a suitable balance and the inclusion of only part of the hoy's image made the picture a stronger one than would have been the case had the boy's legs been included.

Of course, there is a reasonable limit heyond which one cannot go in taking out a piece of the negative to make a whole print, particularly if the latter is to be 8 by 10 or so. This limitation lies in the grain of the negative; the coarser this is the greater the problem of producing a suitable print. However, this difficulty is less troublesome in the larger negatives than the miniature type. In

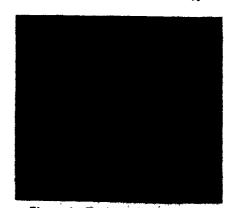

Figure 3: Horizontal composition

Figure 4: The final choice

any event, should a good print be impossible in a larger size, be content with a smaller one. Better a small, good print than a large, bad one.

In the majority of cases, it will be found that a little fussing around with a negative that seems at first glance to be hopeless may prove highly advantageous and result in the saving of a picture that would otherwise have been lost. In short, let the motto be: Crop before you leap—for the waste basket.

COPYING KINK

ERE is an idea from an old-timer that should be helpful when copying faded photographs. Instead of straining the eyes in trying to focus the old, pale image, attach to the copying easel a sharply defined print. When sharp focus is obtained, which should be easy with such a subject, remove the sharp print and substitute the old, faded one. Sharp focus will be assured. This, as you will recall, is based on the same idea as that of scratching a discarded negative and focusing with this when enlarging from a particularly dense negative when the latter, because of the thick silver layer, makes focusing difficult or impossible.

FILM PRICES DOWN

WITH increased consumption of the new high-speed Agfa films, the manufacturers announce they are now able to bring down the price of their films. These reductions apply to Superpan Press film packs, 35-mm Ultra-Speed Pan miniature film, and 35-mm Infra-Red miniature film. All Agfa panchromatic roll films, film packs, and 35-mm miniature films now sell for the same price in each size. Your regular dealer can tell you what the new prices are as they apply to the films you employ.

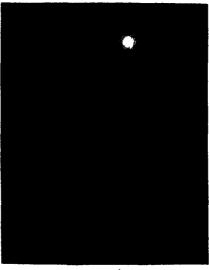

REGISTER YOUR CAMERA

DST of the cameras in the better classes are sold with a registration blank or card on which the buyer is requested to infleate cartain information concerning his ownership of the particular camera, such as his name and address, the serial number of the camera and lens, and so on. These are not provided merely to be impressive, but to

serve as a protection for the camera user. Such registration cards should always be filled in promptly and immediately sent to the address of the manufacturer or importer given on the card. Should the camera be stolen or lost and you do not remember the serial number of the camera and lens, you have merely to write to the manufacturer or importer and request him to look up your card and give you this vital information. This card also identifies you as a user of the particular photographic equipment, and entitles you to new literature as it is issued. It proves your ownership of the particular camera should the issue ever arise, indicates the length of time the camera has been in your possession, thus assuring you service during the full guarantee period, and is helpful in other ways.

"Moon Over the City"

THE exposure required for making pictures by the light of the moon is 500,000 times that called for when the same scene is illuminated by full sunlight. But that does not make moonlight photography as impossible as it would seem, because no one who photographs a moonlit scene wants it to look as bright as the same scene illuminated by sunlight. Let it look like moonlight The picture reproduced here was exposed for 30 seconds at f/3.5. The outline of the huge

By moonlight

shadow mass and the lighted windows are much more realistic and impressive than would have been the complete details that daylight would have shown.

PHOTOGRAPHY ONE OF THE ARTS

THE works of photographers at their best have come to be regarded on a par with those of artists in other fields, and this opinion is subscribed to by no less an authority than Jonas Lie, president of the National Academy of Design. Addressing the preview of the Pictorial Section of the Annual International Exhibition of the Royal Photographic Society, held recently at the Academy rooms in New York City as a guest of the Academy, Mr. Lie said:

"Let me tell you that we do not feel strange in associating with photographers of this quality. We feel very much akin to the pho-

LUMIMAX ENLARGER

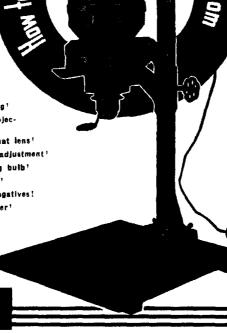

For negatives up to 214" x 214

\$40.00 === COMPLETE Nothing Else to Buy!

- Absolutely rigid in construction!
- Beautiful, large, baked-enamel lamphouse!
- · Thorough ventilation prevents overheating!
- Inside white reflector for brightest projection!
- e Engineed with corrected F4.5 anastigmat lens
- Helical focusing mount for micromatic adjustment
- . Equipped with 60-watt G E enlarging bulb!
- . Highly efficient single condenser system?
- · Interchangeable opai glass for hard negatives!
- . And last, but not least, it has a red filter!

Make the comparison test—where else can you get so much for so little money See the LUMIMAX at your dealer, or write for descriptive literature Dept SA-2

HENRY HERBERT

Have YOU Tried The M.C.M. PHOTOMETER

THE Enlarging Exposure Meter

WHAT IT DOES

- e Tells you exactly how long to expose every enlargement
- Tells you what contrast grade of paper to use with each negative
- Tells you accurately the density scale of any negative
- Lets you turn out Normai Full Scale, Low Key or High Key prints as you desire
- e Gives you an accurate light standard on which to base your judgment for special effects, dodging, printing, etc.
- Can be used with any size enlarger
- No tables or charts to refer to—reads directly in minutes and seconds
- e Will maintain its callbration and last indefinitely. (The G E, bulb used is burned at less than one third its normal wattage.)

It is now in daily use in thousands of dark rooms throughout the world. Ask any one of these users what they think of it. Ask them if it is saving them Money? Ask them if it has improved the Quality of their work—if it is saving them Time? Ask them if it Really Does do the many things we claim for it? We know the answers—Your Dealer knows them, but—

ASK THE MAN WHO USES ONE!

tographers. They have within their power a great deal of what the artist has. The liberties that the photographer can take are almost as limitless as the liberties which the painter is privileged to take. The advance of photography is stupendous and I think we more and more realize what a great art photography is."

The show was held under the auspices of the Oval Table Society, Inc., of New York, a non-profit organization which in the past several years has been responsible for some of the outstanding photographic shows of the country.

PICTURING THE

Jamboree

ONE evening when the weather was somewhat warmer than it probably is at the time you are reading this, we had the interesting experience of attending an outdoor

"The Skeptic"

charity jamboree. A number of tables were set up along the toped off street, each presided over by a lady palmist, sketcher, or person of similar gifts. As we wandered from table to table we sensed the human interest possibilities and shot some candid pictures by the light of the 100 watt lamps suspended over the tables. A fiftieth at t. 4 did the trick on supersensitive pan film. One of the shots was the one shown. "The Skeptie."

"BLACK AND WHITE" OF WATER PHOTOGRAPHY

THE water will show a "white" path where the sun is allowed free rein, as in "White Ripples," but will reveal a "black"

LTIFLEX

NEW YORK, N. Y. 42 FULTON STREET

"Black Ripples"

path where the sun is blocked, as in "Black Ripples" In the latter case, the sun was just back of the boat's mast, in the former, it sent its late afternoon rays clear across the water, since there was nothing to intercept them. Of course, "White Ripples" is a demonstration of reflections of the sunlight, and 'Black Ripples" is an example of the absence of these reflections. On the other hand had the sunlight been coming from the other side it would have illuminated the section of the boat shown in the picture and reflections would then have appeared in the water, though naturally much darker in tone than those of the direct sun light Moreover, were the boat lighter in tone. the reflections in the water would have been proportionately brighter

tem and silvered reflector behind projection lamp. Condenser system removable so that either 50-mm Leica camera lenses or Hektor 85-mm f/2.5 projection lens may be used. Heat absorption filter between lamp and condenser system. Current controlled by toggle switch built into rear of projector.

MICROGRAIN ENLARGING EASEL Makes use of microscope built into framing easel through which actual grain of emulsion is

seen, focusing is done on film grain instead of on image as usual "When focusing with this new device," announce the manufac-

turers, "the magnifying power of the optical system is so great that the image is not seen at all, but when the grain of the film becomes sharply visible the image of the negative is automatically brought into the most critical focus on the surface of the printing paper," Magnification is 15 times magnification of enlarger. Easel provided with quickadjusting paper stops permitting border to be varied to any width. Rigid metal construction with die-cast framing clamps

"S F." REMOTE CONIROL (\$21.50) Robot camera attachment. Operates on electromagnetic principle and works the camera with aid of small dry cell and 15 feet of special light-weight cable. Finished in chrome Can be instantly attached to Robot By simply pressing small button at end of cable, camera shutter is tripped and picture is taken, "Because of the action of the Robot which allows the taking of a series of 24 pictures without rewinding," say the distributors, "the S.F. permits taking almost an entire roll of film without approaching the camera for any adjustments. During the set of exposures, the photographer is not obliged to disclose his presence or efforts to the sub-

MOUNT-O-GRAPH Device for positioning prints on mounts. Centers all sizes of enlargements on all mounts. Resembling T-square, device is simple to use, involving three motions centering picture on mat, lin ing up borders, and determining top and bottom margins

EAE ENLARGER (\$14.75 to \$21.25) 35-mm enlarger featuring new system of illumination (see drawing) employing reflected

light rather than direct diffused light Manufac turers claim coolness of operation, greater protection of negatives, flat-field illumination. Enlarger designed for use with Mod els A and AF Argus cam-

cras or with special enlarging lens and adapter mount, Argus adapter lens (/ 56 triple anastigmat) has aperture slide with 18 and 116 openings Film holder is Bakelite molded, book-type, without glass. Handles either single negatives or strip film. Illumination by 100-watt pre-focused projection lamp, which is placed at right angles to the optical system Thus only the center portion of the lamp, where flattest and most even illumination is available, is picked out and reflected down through condensers.

KALAR TPHOTOGRAPHIC DEVICES

JACOB DESCHIN, conductor of our "Camera Angles" department, will answer in these columns questions of general interest to amateur photographers If an answer is desired by mail, enclose a stamped, addressed envelope Queries should be specific, but Mr Deschin cannot undertake to draw comparisons between manufactured products nor to advise on the purchase of equipment or materials -The Editor

Q. In one of the requests in the Camera Angles Round Table there was reference to "circle of confusion." Is there any definite way of finding this circle of confusion? I would like to know the circle of confusion of the x x f 3.5, 75-mm lens on my camera. Can vou help me?-T. S. B.

4 The 'circle of confusion' designated in calculating a depth of focus table for a particular lens is not a fixed, but is a variable factor, as explained in our reply to P. P. A. in the September, 1938, issue, depending chiefly on whether the resulting negatives are to be enlarged and to what extent. In your case, allowing for enlargements usual with negatives of this size, a circle of confusion of 1 500 of an inch is regarded as appropriate However, a larger disk would be permissible if only small enlargements are to be made

Q. I have recently heard of a new method of printing contrasty negatives called "Tone Separation." The exact details are not known to me. Can you describe it?—F. E. L.

A This was explained by P S Milne in an article which appeared in the January 26, 1938, issue of the English photographic magazine, "The Amateur Photographer and Cinematographer

O Can you suggest a formula for making an ink with which to write on negatives or prints?—L. R.

4 Such an ink may be made up accord ing to the formula given When used on negatives or positives there is a bleaching action which leaves the writing white

Potassium jodide 2 ounces **fodme** 90 grams Gum arabic 90 grains Water 6 ounces

Q. I would appreciate it very much if you could describe for me the elementary equipment and procedure required properly to develop a roll of film.-E.1.

4 Paring available equipment to the barest essentials and having in mind that you prefer the least possible fuss, you will pur chase a "daylight" developing tank; a bottle of liquid developer that may or may not require dilution, as you prefer, or a tube of developer chemicals for solution in an indicated quantity of water, a bottle of concentrated liquid fixing solution or the necessary dry chemicals conveniently available in half pound or pound packages ready for dissolving in water, a graduate, a stirring rod their mometer, and film clips for hanging your negative strip up to dry

The recommendation of a tank may seem an unwarranted expense, but for the man with limited or no facilities the advantage is obvious, it obviates the use of a darkroom The only time absolute darkness is required. is when the film is being loaded into the tank and this step may be accomplished very simply by suffering a few moments of discoin fort behind a heavy barricade of hanging clothes in a closet corner. With the film loaded and the tank firmly closed, the rest of the business may be done in full daylight or electric light

Prepare the developer as indicated on the bottle or package which you purchase, using the staring rod thermometer to star up the solution and to be sure that the temperature of the solution is that required. Pour the developer through the hole in the develop ing tank Leave it there for the required time During the interval get your rinsing water and your fixing solution ready, both at approximately the same temperature as that of the developer solution. When the developing period is ended, pour out the de veloper and pour in the rinsing water. Swish the water around in the tank for a few seconds. Pour out the rinser and pour in the fixing solution. Allow a fixing period of 10 to 15 minutes and pour out the fixer. Then wash for a half hour or so, allowing the water from the faucet to run directly into the tank. At the end of the washing period, at tach a clip to each end of the roll, swab off the surplus water with cotton, and hang the film up to dry, And that's all there is to it.

Q. I recently purchased a copy of your book, "New Ways in Photography," and became very much interested in the chapter on transparencies and their application as lamp-shades, and so on. As a result I am now considering a small business along this line-photographing customers and enlarging upon transparency material. mounting upon a shade, and selling them to the individual customer. First, would I encounter any difficulty with

copyright or patent laws? Second, please specify the required transparency materials. Third, what toners are available for transparencies?—D. W.

A. As to the first question, the making of transparency lampshades has been done for a long while by various methods and many persons. The principle of making lampshades by this method is not patented and is free to be employed by anyone. Second, Eastman Translite materials and Defender Adlux are both eminently suitable for the purpose. Both Translite and Adlux are double-coated, that is, the emulsion is coated on both sides of the paper or film, whichever the case may be. This aids in providing the transparency image with plasticity and roundness. Both materials are available in several standard sizes. Third, since the emulsions are no different from those normally employed on regular printing paper, any of the standard toners suitable for regular papers will do as well for Translite and Adlux.

Q. I wish to use the x x camera for taking pictures of the human eye and would like to have an additional lens tube that would give a normal size image; that is, I to I. How long a tube would be necessary, how far would this place the lens from the eye, and what would be the added time of exposure?—Dr. A. G. S.

A A "normal" or life size image of a subject is obtained at an extension which don bles the focal length of the camera lens That is, with your 2 mch lens, a tube would be necessary that would extend the focal length of the lens to four inches. This same distance should intervene between the leas and the subject so that the total distance, from the plane of the film upon which the exposure is to be made to the focused plane of the subject, is eight inches. The doubling of the focal length of the lens will call for a quadrupling of the exposure time. That is, if the exposure calls for one second exposure with a normal set up, the circumstances will require an exposure of four

Q. Will you please tell me how you dry your 35-mm film? When my film is dry, the sprocket holes are almost touching. I have tried resoaking and re-drying, but to no avail.—L. R.

A Drying 35-mm films requires no special procedure other than that the film strip be freed of excess moisture by passing gently between a "sandwich" of cotton or viscose sponges and then hung up to dry in a dust-free place. You know, of course, that the film has a tendency to curl as it is drying but then flattens out again when drying is completed. Too warm a room temperature or too long a drying time might increase this curling. Dry the film within a half hour or an hour and take it down immediately drying is completed. However, forcing the drying procedure through the agency of heat is not good practice.

Q. When using extension tubes with my miniature camera for obtaining large close-ups of small objects, will you tell me if it is necessary to increase exposure time and how much?—H. K.

A. The use of an extension tube for obtaining actual size or one-to-one images of a given subject will call for a total extension

of the lens to twice its normal distance from the focal or film plane. As a consequence, the f value of the lens will be twice that indicated on the diaphragm ring. For example, if you have a three-inch lens extended six inches from film plane to center of lens, the f/8 value, for instance, will really be f/16 and must be so considered. This will mean an exposure four times that required for the f/8 opening were the normal extension employed. Similarly, with an extension of 4½ inches, the f/8 value will be f/11 and call for an exposure twice normal.

Q. Could you tell me the names of manuals, pamphlets, books, etc., which would give me information on both ordinary and time-lapse photomicrography and macrophotography with an x x 16-mm movie camera?—W. T. H.

A A most practical book on this subject, which is also a story of personal achievement in this field, is "Picturing Miracles of Plant and Animal Life," by Arthur C. Pillsbury A treatise on this subject is contained on pages 323 to 338 of a Smithsonian Report, 1937, by W. N. Kazleff, the title of which is 'Moving Photomicrography "Other works on photomicrography include "Photomicrography An Introduction to Photography with the Microscope," "Practical Photomicrography," by J. E. Barnard and F. V. Welch, and "The Student's Manual of Microscopic Technique," with instructions for photomicrography, by J. Catroll Tobias

Q. Can you tell me how practical is the use of a Photoflood bulb for enlarging purposes?—S. G. N.

4 Completely so, and particularly serviceable when employing the diffuser type of illumination and when a fairly dense negative may take a long time to print, especially where blown up considerably. When controlled by a rheostat device, the Photoflood bulb may be burned at "low" for focusing purposes and then burned at "lugh" for the actual exposure. A housing well designed as to ventilation is important when employing Photofloods Those who disfavor Photofloods in colargers complain, among other things, that the light intensity does not remain constant throughout the life of the bulb, that this intensity is considerably lowered toward the end, that the total life of the bulb is only 112 hours when used this way and that the bulb has a had habit of suddenly burning out in the middle of an exposure. However, take the one with the other and decide for yourself. There is something to be said for either side.

O. What is the best type of material to use in making a photographic light reflector for use as an auxiliary lighting unit?—L. D. K.

A Any white surface will do the work, of course—a newspaper page, a white sheet, and so on However, the most popular home made reflector is an ordinary cardboard covered with sheets of the foil in which films and papers come wrapped, Matt foil is said to give the best diffusion, while others prefer the regular photographic white blotters. Aluminum foil, however, is said to afford better tonal values than the white blotter reflector. When using odds and ends of pieces of this foil in making a reflector it is important to glue them down to the cardboard as flat as possible, flattening them out under a print roller.

NIKOR

Anti-Fog Stainless Steel

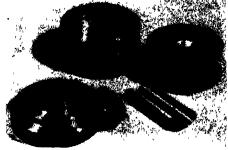

TANKS

NEW ADJUSTABLE MODEL for Cut Film and Film Packs

from $2\frac{1}{4} \times 3\frac{1}{4}$ " to 4 x 5"

Here at last is the adjustable NIKOR TANK for which thousands of serious photographers have been waiting It takes up to 12 cut film or film pack negatives from 2½ x 3½" to 4 x 5" or postcard size Quickly adjusted for any size Film is inserted easily in complete darkness without danger of buckling or scratching. Requires from 24 to 36 oz of solution, depending on size of negative. Made entirely of welded stainless steel that is absolutely impervious to photographic chemicals Easy to keep spotlessly clean Price, complete, only

BURLEIGH BROOKS

TELESCOPTICS

A Monthly Department for the Amateur Telescope Maker Conducted by ALBERT G. INGALLS

IN measuring a room we lay the measure directly on the floor, and we do the same in measuring somewhat finer work, but when it comes to measuring the separation

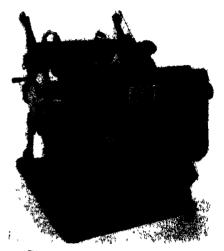

Figure 1: Coordinate comparator

of two star images on a plate this method is not followed by the astronomer: too rough. Instead, he mounts a microscope above the plate, makes provision to move it accurately in two dimensions of space, setting it first above the image of a selected "standard" star and then above that of the star to be measured, and reads off the difference on an accurate scale. At no time does the measure actually touch the plate, and the microscope permits centering by judgment on as indefinite an area as a star image. It magnifies 5X to 35X.

Figure 1 shows a typical measuring engine of this kind, a "coordinate comparator" made by Gaertner for professional astronomers' usc.

First, the carriage as a whole is slid up or down the sub-base, to place the microscope in a comfortable position for the user. On this carriage is mounted the circular stage, showing clearly in the figure. Within it but obscured by other parts, is the plate, set in a square recess. This stage, its periphery di vided into angles, may be rotated by means of the little hand crank shown, and it is rotated until the two star images successively fall under the sliding microscope. The scales are read at each setting and then the angles and position are determined from the readings. The microscope is mounted on a slide and runs on a long, precise screw beneath the slide, a screw having in this instance a periodic error of less than 0 001 mm, or about 1 25,000 inch On the left end of this screw is a drum with a scale and this gives direct readings to 0 001 min. The microscope reticule consists of two hairs set parallel and one at right angles to these Angular separation of the stars may be calculated because the scale of the plate is known or may be computed However, such an apparatus, costing as much

as a fine car, is out of the amateur's reach.

The plate measuring engine shown in Figure 2 was therefore made by Lawrence A Cox, one of the Cox brothers living at 47 Upper Green, Mitcham, Surrey, England, whose telescopes and observatory have previously been described here, and is described by Harold W. Cox They have omitted the circular stage, and they measure by means of a two-stage carriage arrangement, obtaining rectangular coordinates, probably working out the hypothenuse by trigonometry. "Basically," Cox writes, "the instrument

"Basically," Cox writes, "the instrument consists of a frame or plate holder I, to hold the negative or plate, which can be moved accurately in one direction along round rails 2, 3, by means of the fine adjustment provided by micrometer screw 4. These rails are made from lengths of ½" silver steel rod purchased in very straight lengths. Motion at right angles to this is made possible by allowing the microscope 5 to slide on round rail 6 and flat rail 7; it can be moved more accurately by means of micrometer screw 8. The microscope not alone travels on round rod 6 but is hinged on it also, and may fur-

6 10 8 7 13 3 9

Figure 2: The Cox apparatus

thermore be swung back out of the way when required thus.

The micrometer screws 4 and 8, of which 9 and 10 are the extensions, are ordinary heads from L. S. Starrett metric type machine micrometers and permit an adjustment range of 1/2", actually, only 1/2" cm of movement is used. Extension 9 is kept forced against 4 by a spring thrust, 10 against 8 by gravity. When measurements are made between star images more than ½ cm aparts we make use of a glass reference plate or reticule II, ruled with fine lines, which divides it up into sections 1/2 cm square. The plate is a photographic copy of a master ruled plate at Greenwich. Both the microscope and the plate holder can be released from the threaded micrometer extension, moved in position to bring star and microscope coincident, and then locked in position by milled-head clampscrews 12, 13. Position is then read by counting off the lines on the reference plate or reticule and interpolating the rest by adjustment of the micrometers.

The use of the reticule serves to reduce errors which would be cumulative if a long micrometer thread were used instead of the ½ cm movement, also errors caused by curvatures in the rails that carry the moving parts.

"Finally, the microscope itself has a cross-reference, in the form of very fine scratches on glass on a piece of microscope slide cover, made with the sharp edge of a piece of broken quartz rod. Even after several such scratches have been made with the same edge the scratches obtained are finer than those obtainable by most other hand methods. Cross-wires would be much too coarse, as this apparatus has a direct reading accuracy of 0.0001" (inch) on the micrometer scales and, by interpolation, to 0.00001".

"The reticule is always in position and the photograph for inspection is laid on top. The two are illuminated from below by a lamp in a white enameled base. Looking through the eyepiece of the microscope one can see the cross lines in the microscope, the star images, and the lines of the reticule, all in focus at the same time. Sometimes the cross-

lines in the microscope are removed and a fine metric scale engraved on glass is used instead. The lamp in the box 14 is so arranged that direct light does not illuminate the plate, but reflected light from the white walls gives an even illumination over the whole plate. As shown in the photo, the plate holder takes ½ plate size, but with an extra fitting dropped into position any smaller plate can be measured.

"Owing to the fact that any other person making a plate measuring machine would have his own ideas about details I don't think it is worthwhile including them here."

Regarding this, we agree with Cox and the author of page 84: few wish to copy details slavishly.

Figure 3: The Cox No. 1 Schmidt

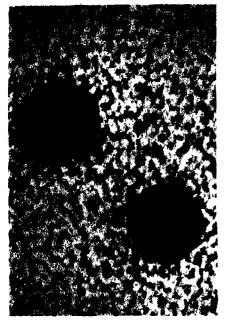

Figure 4: Your scribe's pet sun-spot

SCHMIDT camera (Figure 3) having a 9" mirror and 61/2" correcting plate (hence f 1.5) has also been made by the Coxes, and stellar photographs taken with it and submitted to Lower, of San Diego, California, for opinion elicited the significant response, "the Coxes have made a Schmidt in The images were remarkably fine and round.

Now follows the sad tale of a self inflicted

Figure 5: The Cox No. 2 Schmidt

joke on this department. A little later the two Coxes sent the photograph shown in Figure 4. On the same day came Professor Russell's manuscript for his September article entitled "How Hot is the Sun?" Calculation showed that something was needed to make it fit the usual two-page space-what better filler than this Cox picture? Study closely the familiar solar rice grain background and all its other details. The picture was inserted and given the legend, "Sunspots photographed with a 12" reflector, by L. and H. Cox." The present reproduction is from the same half-tone plate that was shown in September.

Well, as it turned out, the "sunspots" weren't quite that—not precisely. Instead, they were a 140 times enlargement of two star images at the edge of a 16° field taken with the Schmidt camera shown in Figure 3' The photograph had been sent to demonstrate the quality of the Schmidt. Note particularly the absence of coma in the round, clean-cut star images. However, there were

THE BEGINNER'S CORNER

BUGBEARS of the tyro's first telescope include the mounting for the diagonal. From S. R. B. Cooke, Assistant Professor of Metallurgy at the Missouri School of Mines and Metallurgy, Rollo, Mo., and an amateur astronomer, we have received the following:

"Seldom have I seen in your columns a description of a satisfactory, easily made, yet rigid, secondary mirror support. I send a photograph of a type of support which I have used for 15 years in reflectors from 6" to 20" aperture. During that time I have found it to be the essence of rigidity, possessing the added ment of rapid adjustability. I do not claim originality of design, in fact the first telescopes in which I saw it used were those manufactured by Mr. J. T. Ward, of Wanganin, New Zealand. I strongly believe that a similar support was used by Browning, of London.

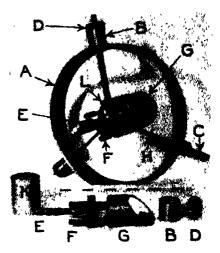

"My first reflector was a six inch, made in 1923 according to the articles by Ellison in English Mechanics The flat support was made of the crudest materials, by the use of simple tools such as hacksaw, file, and a kit of bicycle tools, and it performed perfectly.

"The photograph shows at the top a complete assembly for a 121/4" Cassegrain, and, below, a flat mount from a 101/2" Newtonian, the last-mentioned instrument having been made for selenographical work Istudy and mapping of lunar detail -Ed | A is a strong steel ring, which fits just outside or within the tube proper At positions 120° apart on the steel ring, three bolts, (, pass through square holes cut in the ring. The fit is easy These bolts are riveted to flat strips of spring steel, H, which form the spider. A sleeve, B, fits over the square portion (shown near () of each bolt, and tension on the spider system is maintained by the knurled nuts D The support for the mirror mount is a threearmed steel spider, L, each arm being slotted and firmly bolted to a spring steel spider arm.

"G is a brass tube holding the mirror. It is firmly attached to a circular steel plate by

means of the three adjusting screws F. A helical steel spring fits over each adjusting screw and, for rigidity, is maintained at considerable compression. These springs are shown in the flat mount in the lower portion of the photograph.

"The mirror mount is attached to the spider by means of the elongated nut E. This acrews on to a bolt attached to the circular steel plate, and which passes through a hole bored or drilled in the heavy steel spider. E is long, to facilitate attachment in the relative gloom of the interior of the tube.

A secondary-support assembly

"The secondary mirror is adjusted centrally by the knurled nuts D. Collimation is effected by the adjusting screws F.

"K is a light-weight metal cover which slips over the brass mirror mount when the telescope is placed away for the night.

"Professor W H. Pickering stated that the New England climate was the world's worst, as far as observing was concerned It could not possibly be worse than the Ozark climate, in this respect. After ten years of it I find myself longing for the steady New Zealand atmosphere"

When a prism is used for a diagonal the moint will of course be modified accordingly Few types will need so fine a mount

TELESCOPTICS

(Continued from preceding page)

signs of coma elsewhere for your scribe went straight into a coma, especially when it turned out that the photo had been correctly described in the original Cox letter Hereafter, this department is wearing two pairs of specs.

Several months have elapsed since the misnamed photograph was published. No reader has written the editor to apprise him of the error. No doubt all you readers noticed it, of course! For kindly forbearing to write in about it all are thanked. Their innate tenderheartedness has been quite touching.

So your scribe's face is red, red, red, almost infra-red, and now at sight of a sun-pot picture he simply breaks down and sobs.

ORE recently the Coxes have sent Figure 5, showing their No. 2 Schmidt job, an f/1.5 with a 12" f/0.75 primary and a 612" correcting plate. It covers a full 20° field. The cell for the correcting plate is all metal and alone weighs 120 pounds. Two

doors, similar to those in Figure 3, show slightly on top of the tube; these bed down on rubher seatings.

To the Journal of the British Astronomical Association, Vol 48, No. 8, the Coxes have contributed a 5-page article describing their work in figuring the correcting plate and making the film holder. Too long to reprint here, your scribe will lend it for a brief time to any who seriously aspire to make Schmidts.

POURTH Cox item is a chronograph (Figure 6) "for use in our observatory," as they describe it. "We experimented with various forms of recording, one of them being that of burning holes in the paper by an electric spark. The voltage of the ordinary house supply was stepped up by a transformer, about 700 volts proving best for the paper we were using, and one side of the output was connected to a platinum point fixed to the armature of the magnets and the other side to the metal track over which the paper runs. The impulse from our clock, a Synchronome having an accuracy of about one second per month, actuated the magnets,

bringing the platinum point into contact with the paper, which was not sufficient to act as an insulation from the metal track.

"However," they continue, "this method was abandoned, as the sparks made interference with the radio used for giving clock checks against Greenwich. (We did this by connecting the radio receiver in place of the personal switch and then comparing recordings of our clock against that of Greenwich, and by this method we can check to an accuracy of about 0.1 second every day.) We are

Figure 6: The Cox chronograph

now recording with the two siphons shown in the photograph, fed from a small tank of ink fixed to the inside of the track. One of these is fed from the seconds contact on the clock and the other from the half minute impulses and also from the personal switch"

PRINCIPLE of a simple micrometer for measuring angular diameters, also for relative measurements of detail on Jupiter and other planets, is shown in Figure 7, redrawn from a sketch by F L Frazinc, 1016 17th Ave. N., St. Petersburg, Fla. Adapter tube for connection to telescope. Brass plate soldered to this. To that, in turn, is soldered

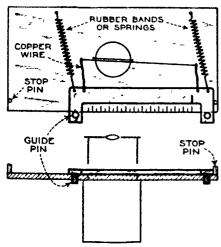

Figure 7: Frazine's micrometer

a bracket to support eyepiece, the eyepiece alone being sketched in on the drawing. Rider on plate.

Lap one edge of plate straight Drill %" hole in center Cement silk fiber or spider web across hole and at small angle with straight edge of plate Second fiber is cemented to copper wires shown, and adjusted parallel and precisely over the first by bending these wires. At same time rider is at right-hand stop, "As I have constructed it." Frazine says, "the full scale reading equals 50 seconds and the scale is in 25 divisions. I find the micrometer is accurate to about 1 second of arc. To calibrate it, I timed a star from web to web when the webs were set wide spart,"

MANHATTAN ELECTRICAL BARGAIN HOUSE, INC., Dept. S.S., 105 Fulton Street, New York City

PROCEDURES IN EXPERIMENTAL **PHYSICS**

By John Strong, Ph D

THE experimental, in contradistinction to the theoretical, physicist must be thoroughly at home in the laboratory, devising and inventing, constructing a wide variety of apparatus, and capable of doing refined mechanical work in many trades and skills. Laymen frequently inquire for treatises on these skills, only to learn that many of them have never been exposed in written form; one scientist learns direct from another-if he happens to be near that other. Now, in this unusual book, Dr Strong. the well-known pioneer of the process of aluminizing mirrors by evaporation, assisted by four other scientists who have mechanical leanings, has assembled a wealth of useful data of a wholly practical kind for the constructor, experimenter, and skilled craftsman. In 15 chapters the following are covered. laboratory glass blowing, optical work; high vacuum technique, evaporation and sputtering; using fused silica, electroneters and electroscopes, Geiger counters, vacuum thermopiles, light sources, filters, and optical instruments, photo-electric cells and amplifiers, photography in the labora tory; heat and high temperatures, materials of research, construction and design of instruments and apparatus; molding and casting The many clear, lucid illustrations, drawn by a man who comprehends the work himself, reveal fully as much as the text Advanced amateur telescope makers will discover that the chapter on optical work presents in detail the methods of D. O. Hendrix, head optician at the Mt Wilson shops-the first time a professional optician has made his methods public. The valuable illustrations of this chapter were drawn by Roger Hayward, an amateur telescope maker and architect (642 pages, 6 by 9 inches, numerous illustrations.) -\$5.10, postpaid .-- A G I

COLOR PHOTOGRAPHY FOR THE **AMATEUR**

By Keith Henney

OUESTIONS constantly arise in the minds of amateur photographers regarding the possibility of working with color. Is it difficult' Is it too expensive? Are the results worth the necessary efforts? The author of the present book has answered these questions in clear and concise style, giving the amateur photographer all the available information regarding the various color pro cesses-fundamental principles, films and filters, transparencies, separation negatives, and color printing processes. He names names and estimates costs. (281 pages, 6 by 8½ inches, illustrated, including several color plates 1—\$3.60 postpaid.—A P P

THE YANKEE CHEESE BOX

By Robert Stanley McCordock

IN the histories of the navies of the world there was probably no other departure from traditional naval principles so sudden and of such enormous significance as the construction, during our Civil War, of the

Books

SELECTED BY THE EDITORS

ironclads, the Monitor and the Merrimac. Here we have the fascinating detailed account of the construction, the incidents leading up to the important battle between these two vessels, the battle itself, and the comment of newspapers and experts throughout the world. Chapter heads will indicate the scope Dixie Experiments, Swedish Genius, A Strange Craft, "Ericsson's Folly"; Panic Grips the North; The North Hails the "Cheese Box"; The Confederacy Rejoices; The Demand for Ironclads, The North Dreads the Merrimac's Return, John Bull Studies Naval Architecture, and so on throughout the existence of these two tradition-breaking vessels. This concise story of the first fighting ironclads is as interesting as it is important (470 pages, 5\% by 8\%)
-\$3 10 postpaid --F. D. M.

SUNDIALS

By R. Newton and Margaret L. Mayall

THE best book on sundials. Its authors, $oldsymbol{1}$ one a landscape architect, the other a professional astronomer, published nine articles on sundial design in Scientific American in 1934-35. Those articles, with much added discussion and instruction and many fine photographs of unusual dials, are now embodied in this all-around book which gives instructions for designing precise dials that tell the time and are far more than con venient bird roosts to ornament the gardens of unscientific people. A really practical book (197 pages, 51/2 by 73/4 inches, illustrated) -\$2.10 postpaid. -A. G. 1.

SUBMARINE

The Autobiography of Simon Lake as told to Herbert Corev

AMONG the important inventions of the past century, that which gave us the modern submarine is outstanding. While Simon Lake was not the inventor, he was one of the earlier developers and the story of his trials and tribulations in working with this monster of the deep makes fascinating reading, Mr. Lake is a colorful character indeed. He has definite ideas regarding the future of the submarine both in war and peace, and

We can supply our readers with any We can supply our service of the books reviewed in this department. Prices quoted include do-mestic postage. Foreign prices are necessarily higher due to increased shipping charges.

SCIENTIFIC AMERICAN 24 West 40th Street New York, N. Y.

these, too, make interesting reading. We hope that he is wrong in making this statement. "I do not believe that a battleship can be built that will be impregnable under sub-marine attack." (303 pages, 51/2 by 81/4, itlustrated.) -\$3.10 postpaid.-F. D. M.

ELECTRIC WELDING

By Morgan H. Potter

PRACTICAL in every sense of the word. this book covers the fundamental principles of the various types of electric arc welding, describing equipment and methods for obtaining the best results under varying conditions. It deals with the various types of metals that can be welded, and tells specifically how the process should be carried out with each, (77 pages, 6 by 9 inches, a large number of drawings and photographs.) -- \$1.35 postpaid -- A P. P.

WOOD PRESERVATION

By George M. Hunt and George A. Garratt

COMPREHENSIVE treatment of the A subject of wood protection against decay, insects, and other agencies of deterioration. Covering first the field of wood preservation and agencies of wood deterioration, this volume proceeds to discuss in minute detail wood preservatives, preparation for treatment, processes, properties of treated wood. and related subjects. Architects, executives, foresters, lumbermen, treating-plant operators, and others will find it a valuable reference volume. (457 pages, 61/4 by 91/4, well illustrated.) -\$5.10 postpaid.-F. D. M.

TRADE MARK— LAND MARK

IN a decision of monumental importance in trade-mark law the Supreme Court of the United States upheld the exclusive right of the plaintiff to use the trade mark NU-ENAMEL on enamel paint products and sustained the validity of the registration of the trade mark under the Federal Trade Mark Act of 1920.

Under the common law, descriptive words were not regarded as valid trade marks hecause it was believed that to confer upon anyone the exclusive right to use such words in connection with a product would unduly restrain competitors in the description and designation of their products. Slowly but surely, however, the doctrine of secondary meaning has developed. Under this doctrine where, through prolonged exclusive and extensive use of a trade mark, a descriptive name has acquired a secondary meaning indicating the source or origin of the merchandise to which it is applied, the name will be protected as a valid trade mark. The Federal Trade Mark Act of 1905 which provides for the registration of trade marks does not recognize the doctrine of secondary meaning and descriptive words cannot be registered as trade marks under this act. This led to certain practical difficulties, one of the most serious of which was that American concerns engaged in international business were unable to register their trade marks in foreign countries unless they were first registered in the United States and consequently owners of descriptive trade marks, being unable to register them in the United States, could not register them abroad. To meet this situation a trade-mark act was passed in 1920 which permitted the registration of descriptive

There is a very important distinction between the Trade Mark Acts of 1905 and 1920. A registration under the Trade Mark Act of 1905 is prima facie evidence of ownership by the registrant. This is not true of a 1920 registration. Prior to the present case there has been a great deal of uncertainty as to the nature and scope of the Trade Mark Act of 1920. In the present case the Supreme Court held that under the Trade Mark Act of 1920 a descriptive word may be registered as a trade mark. The Court also held that a registration under the 1920 Act gave the registrant the right to sue in the Federal Courts and to recover treble damages should the defendant be found to infringe the trade mark. The principal distinction between registrations under the 1905 and 1920 Acts, according to the Supreme Court, is to be found in the fact that since the 1920 registration does not carry with it any prima facie

evidence of ownership it is necessary for the registrant to prove in court that he is the owner of a trade mark registered under the latter set.

In the present case the Court found that while the words NU-ENAMEL were descriptive they had been so widely used and extensively advertised by the plaintiff that they had acquired a secondary meaning indicating that the enamel product so labeled originated with the plaintiff. Under these circumstances the Court held that the trade mark was valid and was the exclusive property of the plaintiff. The importance of this decision resides in the fact that the Supreme Court has recognized the following principles:

1) A descriptive trade mark may be registered under the Federal Trade Mark Act of 1920. 2) A descriptive name or word may become a valid trade mark if it acquires a secondary meaning. 3) The owner of a 1920 Federal Trade Mark Registration is entitled to bring suit in the Federal Courts for treble damages against an infringer.

MUFFLED

An individual is sometimes restrained from manufacturing and selling an article which the rest of the public has a perfect right to make, use, or sell. This situation arises where the individual acquired information regarding the article by unfair or fraudulent means.

This principle is illustrated by a recent case in New York in which a manufacturer of silk scarfs or mufflers sought to restrain a competitor from manufacturing a similar scarf or muffler. Plaintiff had conceived of the idea of printing on a scarf, in which the pattern depicted football and other collegiate scenes, a pennant with the authentic color, seal, and name of a particular school or college To reduce the expense of manufacture the plaintiff had his printer prepare a master screen for printing all of the scarf with the exception of the pennant. The master screen was formed so as to accommodate a small insert screen which would print the pennant on the scarf. In this way the same master screen could be used with different insert screens so as to print scarfs having the pennants of the many different colleges. The Court found that the printing of scarfs in this fashion was an original creation and that certain former employees of the printer who prepared the screens for the plaintiff and who had acquired knowledge as to the manner of printing the scarfs while employed by the printer subsequently, for a consideration, made for the defendants a copy of the distinctive screen employed by the plaintiff. The Court also found that the defendants knew

that the former employees had acquired the information when employed to make scarfs for the plaintiff and that they were fraudulently abusing the trust which had been imposed in them when they imparted this information to the defendant. Even though the scarfs had been published the Court held that it would restrain the defendants from manufacturing, exhibiting, and selling scarfs of this type because they had acquired the information by unfair means.

In this connection the Court stated:

"Defendants had a legal right to copy and to sell as their own creation the exclusive model designed by the plaintiff if the model or an inspection was procured by fair means, but defendants had no right to obtain the plaintiff's trade by unfair means."

PAJAMA CRISIS

If by chance any of our readers are of such a temperament that to enjoy a good night's sleep they require individual and distinctive pajamas, we recommend that they patent their pajamas.

In a recent case for unfair competition involving paiamas the Court held that in the absence of patent protection anyone is at perfect liberty to copy the pajamas made by another. In the case in question, the plaintiff manufactured a man-tailored type of pajamas for women, having withy statements and slogans imprinted on the garment. The plaintiff contended that the defendant had copied its pajamas and asked for an injunction to restrain further copying.

The Court refused to grant an injunction, stating:

"Since plaintiff has placed the pajamas upon the market without securing the protection of the Patent Laws, it thereby published the design of the pajamas and no longer has any exclusive property right * * * In the absence of a showing of any unfair competition, such as an attempt by the defendant to mislead or deceive the public or to 'palm off' its product as the plaintiff's, equity will not aid plaintiff by restraining another from copying and selling the article in question"

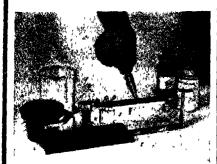

WHAT IS A BOOK?

WE have heretofore pointed out on this page that dictionary definitions and popular interpretations of the meaning of words are sometimes disregarded by the copyright law. An example of this is the rather liberal interpretation given to the word "book."

A recent suit for copyright infringement involved a copyrighted chart to be used in analyzing handwriting. The chart consisted of a single sheet of paper divided into small rectangular subdivisions, each subdivision containing an illustrative specimen of handwriting and a description of the supposed characteristics of a person having that type of handwriting. The Trial Court held that the chart was not proper subject matter for copyright and dismissed the suit. The Circuit Court of Appeals, however, disagreed with the Trial Court and sustained the copyright. In reaching its decision the Court of Appeals pointed out that under the rules of the copyright office the chart was a book and that a book was proper subject matter for copy-

An Accurate Balance

at a price within the reach of all

Sensitive to 2/50 gram Weighs up to 100 grams Compact—No loose parts Modern, durable construction Small convenient size Handsome streamline design

Now permissible for auxiliary use in drug stores (N. Y. C. Serial B17.)

Never before a balance with all these exceptional features!

Finest Quality-Made of tested materi als. Its construction will appeal to laboratories desiring the best equipment. The Bakelite cup is unaffected by practically any substance that can come in contact with it the tool steel knife edge and agate bearing will give long life and accuracy

Extreme Sensitivity--Weighs to one decimal point farther than the usual lowpriced counter scales and serves nearly every laboratory purpose short of precise analysis The capacity of 100 grams is ample for the delicate weighings made in the usual course of teaching, organic synthesis, experimental work, compounding, photographic work, etc.

Compact-Convenient-Does not monopolize a laboratory table. Placed on the desk of the busy technical executive, it will soon become indispensable

Its small size makes it possible to carry it on inspection and testing trips at a distance from the laboratory. It is small enough to be carried under the aim or in an overcoat

Graduated in either the Metric System (grams) or the Apothecary's System (grains, drams and ounces). In ordering, please indicate which of these you desire.

Industry Is Sold!

More than any other agency, institution, organization, or magazine, Scientific American has sold the products of all industries to the world!

¶Industry is built on scientific research, invention, applied science. ¶For 94 years, Scientific American has described these achievements, interpreted them, evaluated them. ¶Readers of Scientific American know scientific principles, have been sold an understanding of the science behind all industry. ¶In buying, they rely, not on advertising catchwords but on sure knowledge of scientific construction or composition, operation, and efficiency.

HENCE Scientific American is a national—an international—institution, standing alone and unchallenged, for disseminating scientific knowledge to a receptive audience, for selling scientific principles, for educating its readers to be guided, in buying, only by the technical excellence of a product.

A NATIONAL INSTITUTION

THAT is why the Cream of American Industry—nationally noted corporations, corporation executives, research men, those who influence or control the vast purchases of all industries—watch Scientific American closely, read every issue. Editorial coverage of achievements is "high-altitude horizontal," not "vertical" as in a trade journal. Each issue not only

gives the reader usable facts regarding his own industry, but also tells him of developments in others that may have great significance or use in his own. Such facts have inspired new inventions, discovered new and unthought of uses for new developments, shown how enormous savings and profits could be made. Innumerable letters to the editors are our evidence.

SCIENTIFIC AMERICAN—PROMOTER OF PROGRESS

Its editors probably sold one or more of your products to the world long before the effects of your own advertising were felt—as soon, in fact, as the products left test tube or laboratory.

If your product is based on science, has technical excellence, requires specialized selling to a selected audience, then complete the selling job our editors have done by using our advertising pages. Ask us for rates, details, and copy of our publication "BILLIONS IN CAPITAL READ SCIENTIFIC AMERICAN".

A Complete Mastery of **MATHEMATICS**

Prepare now to advance yourself to an important job by Mathematics Training Mathematics is the foundation of all mechanical and scientific work, and of all business or industry based on science Without this essential knowledge even the most capable man is left behind while others forge ahead to better jobs, bigger contracts, more money You need mathematics to solve technical problems and to improve, speed up and check on your work and the work of others

Now you can learn mathematics by an easy, inexpensive and time - saving method A very simple and extremely interesting course in book form

for you by an expert who has devoted a lifetime to teaching practical men the fundamentals of this important subject

MATHEMATICS FOR SELF-STUDY

By J. E. Thompson, B.S., A. M., Dept. of Mathematics, Pratt Institute

These books start right from the beginning with a review of arithmetic that gives you all special short cuts and trick methods that save countless hours of cuts and trick methods that save countiess nours of your time. Then they go right into higher mathematics and show you how simple it is when an expert explains it for you. In no time, it all you will be tacking with case the most difficult questions on this subject.

THIS QUICK EASY WAY

IMPROVE YOUR APPEARANCE

By the Magic of SUNSHINE

85% of success today is due to personality and ability to influence others

. . according to an exhaustive study recently made at Carnegie Institute of Technology

That pale, pasty in efficient, indoor look

is a business and social handicap. Why put yourself at such an unforgivable disadvantage when you can get that hand-some, healthy T.1N everybody admires so much right in your home? Within ten days, you can improve your appearance remarkably—look like a million dollars—as if you had just returned from a vacation in Palm Beach!

Produces VITAMIN D

Aids Calcium and Phosphorus Deficiency

blemishes and pimply complexions. Let your physician advise you it you wish for your particular ailment.

As leading makers of sun lamps in Amer ica, we have developed lambs to suit the needs of every pocketbook. We have single are lamps using 2 carbons and having intensity of 412 times mid-summer sunlight as well as double are lamps using 4 carbons and having an intensity of 10 times mid summer sonlight. Also there is available the Palm Beach De Luxe Model (Double Arc) having the same intensity as lamps used by hundreds of clinics and thousands of doctors throughout the United States Just think of it—a 4 min utc exposure gives you the equivalent of 50 nunutes mid-summer sunlight. We are the first company in the United States that has developed a Double Arc Lamp (4 carbons) of this power at a price so low that it is within the reach of almost everyone

AS LITTLE AS \$1.00 DOWN

Any of our models can be purchased for as little as \$1.00 down and the balance can be paid in easy payments. There is a Palm Beach model for every pocketbook—every model can be bought on easy payments and every model is subject to our 10-day Free Trial. Guarantee

The Trial Sunshine at a BARGAIN

There is no need any longer, to envy the fortunate few who are able to go to Florida each winter and it's not necessary to spend a "small fortune" to get the benefits of the vital Ultra-Violet Rays of sunlight during cold, dreary winter days

INEXPENSIVE—EFFICIENT The Sun Lamp That Tans Quickly

The new, inexpensive, Home Model, Palm Beach Mercury-Arc

COLD Ultra-Violet Ray Sun Lamps give you your own private solarium in which to TAN and keep healthy These lamps are designed to meet the fast growing demand for low priced home units that are dependable and economical They have all the beneficial qualities usually found in higher priced Mercury-Arc models

Daily exposure of only 3 to 4 minutes per day will help to improve your appearance and health Will give you that HEALTHY TAN that everyone admires make you independent of weather conditions or season of the year You get vital Ultra-Violet Rays at the mere turn of the switch

Almost Pure Ultra-Violet Rays

The special type Palm Beach burner is highly efficient and more than 90% of the energy emissions are in the middle Ultra-Violet Ray region, affording a source of almost pure Ultra-Violet Ray radiation

PRODUCES VITAMIN D Will Cure and Prevent Rickets

Radiation from the Palm Beach Home Model, Sun Lamp, produces Vitamin D... aids calcium and phosphorus deficiency Powerfully anti-rachitic... will both prevent and cure rickets and help build resistance to colds and other winter ailments Rays are bactericidal in action, and will produce erythema

(TAN) in half the time of ordinary sun lamps

The Palm Beach Mercury-Arc COLD Ultra-Violet Ray Sun
Lamp helps increase youthful vigor and vitality and tends to
stimulate glandular functions Remarkably beneficial in some
forms of skin trouble. Often decidedly effective in cases of listlessness and anemia; many forms of sinus conditions are greatly
benefited. Mercury-Arc Sun Lamps have been used by the Medi-

WALKING barefoot on a broad bed of red-hot embers, as shown on the front cover, is a feat performed by Hindoo fire-priests, to the exaltation and emotional frenzy of the natives. Supposedly supernatural, the performance has now been studied by scientists, and a detailed report of their findings appears in the lead article of the present number (page 135). It turns out that there is no magic trick and no deception to the feat, which is honestly performed.

SCIENTIFIC AMERICAN, March, 1939 Vol No. 160, No. 3. entered at the New York, N. Y., Post Office as second class matter June 25, 1876, under the act of March 3rd, 1879, additional entry at Greenwich, Conn. 50 Years Ago in . . .

(Condensed From Issues of March, 1889)

DIPHTHERIA—"It is claimed that 'two professors connected with the Pasteur Institute have discovered the generative microbe of diphtheria, and that a preventive of this disease by means of vaccine virus is expected to follow. Should this expectation be realized, the discovery and its successful application will certainly take rank among the most important triumphs in the realm of medical science."

LINOTYPE.—"The accompanying illustration represents the latest, and in many respects the most remarkable, of the numerous ma-

thines which inventors and mechanics have from time to time devised in their long-continued efforts to find some practical means by which to supersede or out short the tedious work of typesetting. It is known as the Linotype machine, from the nature of its prodnet . . . It is not, strictly speaking, a typesetting machine, but forms type bars, each of the length, width, and height of a line of type. and the exact counterpart of that which a compositor would set up, except that each line is formed of one entire piece of metal, instead of as many different pieces as there are characters, spaces, etc. . . . The key-board in front of which the operator sits has 107 keys, each marked for a

capital or lower case character of a font of type, or the figures, points, or compound letters used in connection therewith, many of the letters most frequently used having several keys."

MEXICAN RAILROAD—"The engineers of the Mexican Southern Railway have laid out the lines as far as Tecomavaco, 58½ miles south of Tehuacan.... The new line will carry the American and Mexican railway systems some 300 miles farther south, and will shorten the time from Europe and New York to South American and Pacific ports from a week to ten days in the former, and four to five days in the latter case."

BIG GUNS—"Two monster Russian guns were sent recently to Sebastopol... for the purpose of being placed in the new ironclad Sinope, and although some of the details must be inaccurate, the official description is too interesting to be ignored. They are 12-inch pieces, weighing 50 tons, and throwing projectiles of nearly half a ton. The powder charge is 270 pounds, and the initial velocity 3000 meters [sic], while the distance of the cannons' ranges is said to be 20 versts, or over 13 miles."

MAGNET—"The direct use of electricity as a labor saving machine has been applied at the great steel works, Cleveland, Ohio, where a large electro-magnet is used, suspended from a crane, to pick up steel bars and billets. It will pick up 800 lb. billets and drop them where wanted, by the touch of a key, the movement of the crane being done by steam."

SMOKE—The weight of the great smoke cloud daily hanging over the city of London, England, has been computed by Prof. Roberts

at 50 tons of solid carbon and 250 tons of hydrocarbon and carbonic oxide geses for each day of the year, and its value at \$10,000,600 per annum."

INVENTION—"Nine-tenths of the material prosperity of this American Union is due to inventors and their patents. A volume would not suffice to relate the many obligations we owe to the men whose patient investigation and ingenuity have cheapened processes and lessened labor for this prosperous people. Rather let us remove our

hats before the man who has devised a machine by which we may get bread with less sweat."

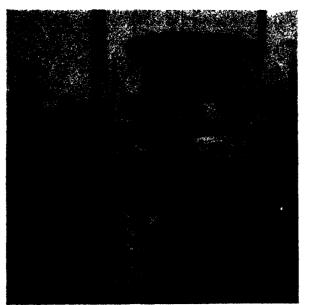

LIGHT..."So far as we know, every city in the United States is now provided with arc and incandescent illumination, and the introduction of electric lighting is rapidly extending to the smaller towns. Already hundreds of villages of only a few thousand inhabitants have their electric light plants."

FUEL—"It has been demonstrated in Vaca Valley that peach stones will make as good a fire for household purposes as the best kind of coal in the market.... The fruit growers, instead of as heretofore throwing the pits away, dispose of the stones at the present time at the rate of \$6 a ton. A sack of the stones will weigh about 80 pounds and will last as long as an equal number of pounds of coal, and give a greater intensity of heat"

TELEPHONE—"The Metropolitan Telephone Company, of New York, have recently erected a new central station building in

Cortlandt Street, which is of special interest as embodying the latest improvements in telephone central station work and accessories, as well as containing the largest switchboard in the world. At present about 2500 subscribers use it, but all the connections are prepared for 6000, and the board can be extended so as to include 10,000. The building is fireproof throughout."

EIFFEL—"The question of the possible use of the Eiffel Tower for scientific purposes has been often raised, and as yet we have seen no authoritative document on that head signed by any scientific man or indorsed by any learned society, but scientific utility is possibly a secondary object in its construction. The tower will be such a curiosity in itself as to powerfully help to draw many visitors to Paris during the exhibition."

OUR POINT OF VIEW

The Picture Falls Together

FOURTEEN years ago the anthropologist and anatomist, Sir Arthur Keith, ablest authority among scientists on the skeletal remains of ancient man, concluded his notable work on "The Antiquity of Man" with a significant reference to the genealogical tree of human evolution as that tree was then known. "We may hope," he wrote, "to find many more branches." He sensed fully that the five humanoid types at that time known represented probably but a few fossil twigs of what would turn out later to be a many-branched tree of man, ape-men, and apes of the past.

On that tree were the Java ape-man, Pithecanthropus erectus, earliest offshoot from the main stem and 500,000 years old; Neandertal man, Piltdown man of England; Rhodesian man; and finally our own modern races and some of their nearer ancestors such as Boskop man, Talgai man, and Wadjak man-the widely-known Cro-Magnon man being the probable ancestral type of our own European race.

How extremely ably Sir Arthur Keith prophesied has been amply borne out by the subsequent progress of discovery In brilliant succession has come major find after major find. In and after 1927 came the several skulls found excellently preserved in caves near Peiping-Sinanthropus, or Peking man, curiously combining modern and primitive characters and contemporaneous in age with the Java ape-man. In 1932 came the 50,000year-old skull of Solo man found also in Java, a probable descendent of the Java ape-man In the same year came the discovery in Palestine of 13 whole skeletons of a race in part like Neandertal man but greater in antiquity In 1936 and 1937 two new skulls of the Java ape-man afforded the necessary evidence to throw him out of his former ape-man status and almost into the human trend of evolution. Truly, paleoanthropology, the science of ancient man, has been actively on the move.

In addition to these discoveries there is the remarkable series in South Africa. In 1924 at Taungs, the fossil skull of a previously unknown type of ape, much nearer to man than the chimpanzee or gorilla, was found by Dart. In 1936, at Sterkfontein, Broom, a physician-anthropologist, discovered the skull of an ape differing from the living apes and named it Plesioanthropus. In 1938 he found at Kromdraai the skull of another type of large ape and named it Paranthropus. Both are of Pleistocene age-dating from

some scores of thousands of years ago.

And now has come the cap to the climax. Supplementary finds of arm, leg, and foot bones more recently discovered by Broom show clearly that these supposed apes walked erect and were probably nearly human.

Thus the mosaic is being rapidly filled in and the picture of the evolution of man from his ancestor begins to emerge. The prediction that more and more fragments of this picture will come to light is easier today than it was when Sir Arthur Keith predicted major finds The American anthropologist Hrdlička has always urged that science was trymg to build the picture on too few and uncertain fragments. In a relative sense this still remains true but the signs grow better. Prof. H. H. Wilder united man and the living apes in one family, a courageous act! Since Nature must have experimented with numerous others now extinct-a whole welter of forms intermediate between man and the living apes, whose fossils are likely to be discovered-the prospect for those who will be here to watch the progress during the next 25 or 50 years is likely to be decidedly interesting .- A. G 1

If They Would Only Learn

DEDESTRIANS who are familiar with automobile operation stand a better chance of keeping out of traffic trouble than do those who lack this advantage This definite conclusion is drawn from evidence that, of the 15,000 pedestrians who are killed in traffic accidents yearly, the majority do not know how to drive.

Those who walk, of necessity or by choice, have certain rights that cannot be disputed by any fair-minded automobile driver. But it is hardly fair to all concerned to uphold these rights regardless of the inclinations or desires of the pedestrian. The one factor that must be considered is the relative maneuverability of the walker and of the motor car. While the man on foot travels at a much lower speed than the motor car, he can jump, dodge, or change direction much more rapidly than can the faster moving and more bulky motor car. Then, too, the pedestrian from his more stable vantage point is often in a much better position to judge the speed of an oncoming car and be governed accordingly, than is the driver who has so many things to watch at the same time.

The point is this: The driver is familiar with both walking and driving; the pedestrian often is familiar only with his own pedal means of locomotion;

would it not contribute to the peace of mind as well as to the bodily health of all if these two groups were placed on an equal footing of knowledge and hence of judgment? A start has been made in some sections where the fundamentals of automobile operation are taught in schools, thus providing the pupils with information that may later be instrumental in saving their lives,

It would be far better if every person, regardless of age, could receive the benefit of this sort of education. It is, of course, too much to hope that such a thing could be accomplished by compulsory education, but thinking people who do not own motor cars can take the lesson of statistics to heart and provide for their own safety. If these pedestrians will take the time and trouble to learn how to drive a motor car, even though they may never have occasion to do so, they will have laid a foundation of knowledge that will be as important to their futures as are the simple rules of health and sanitation. -- A. P. P.

The Implications of Science

THE demand that screece many world to utilize its accomplishments social PHE demand that science help the constructively, for the common social and economic good, has been so urgent during the last few years that a plan has been worked out to do just that, according to a recent announcement. However, the plans will not be revealed until after consideration by the Council of the American Association for the Advancement of Science.

Naturally, every right-thinking per son will welcome this new activity and wish its leaders well in their attempt to integrate the work of scientists. Yet we cannot suppress a certain cynicism, Science, no doubt, is far ahead of civilization, but if this is so, attention should be paid to education of the human being, not to the end-product of research Who, for example, could have foretold the bombing airplane's domination of cities or its dictation of new national boundaries; or, having done so, could have thwarted this "misuse" of a scientific product except by education? Furthermore, that the planners worked for three years "in co-operation with a Congressional committee," reminds us too much of the useless 450,000-word report of the National Resources Committee.

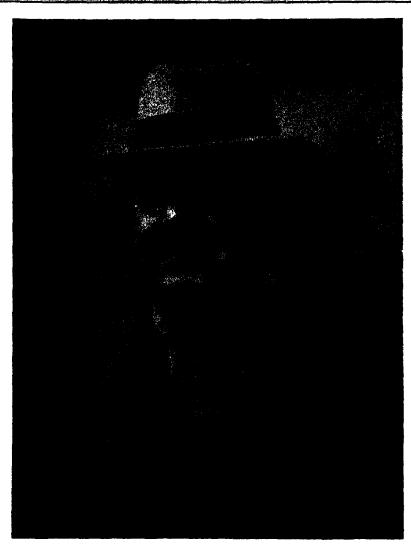

Perhaps our cynicism is ill-founded. We hope so. But we will look for real results and be content with nothing less. "Reformitis" for its own sake is too much for stomachs far from queasy.-F. D. M.

Personalities in Science

CONFUTING an occasional American impression that in England a man's rise in rank is heavily hampered if he does not happen to belong to the right class, is the career of Sir Richard Gregory, for 20 years the editor of Nature, the world's most outstanding journal of the sciences for the professional. He began life as a newsboy, in accepted American fashion, and many years later was knighted and given the hereditary rank of baronet by the King.

Richard Arman Gregory was born in 1861 After leaving school at 12 years of age, he became in succession a newspaper boy, page boy, machine boy in a printing office, and apprentice to the boot and shoe trade. Through his studies before and after factory hours, he was brought to the notice of Dr. J. M. Wilson, then headmaster of Chiton College, and was given a minor post in the physical laboratory of the College. From there he was successful in gaining a studentship at the Royal College of Science, London, which entitled him to free tuition and a maintenance allowance of about five dollars a week. After leaving the College, he became science instructor at H M. Dockyard School, Portsmouth, but returned two years later to become a research assistant to the great astronomer, Sir Norman Lockyer, who in 1868 discovered in the Sun what was then an unknown gas, named by him helium, which was not identified on the earth until 26 years later. In 1893 Sir Richard became associated with Sir Notman as assistant editor of Nature and succeeded him as editor in 1919 For several years while engaged in the editorial work of Nature, Sir Richard was an Oxford University Extension Lecturer and professor of astronomy at Queen's College. London.

Among the academic honors conferred

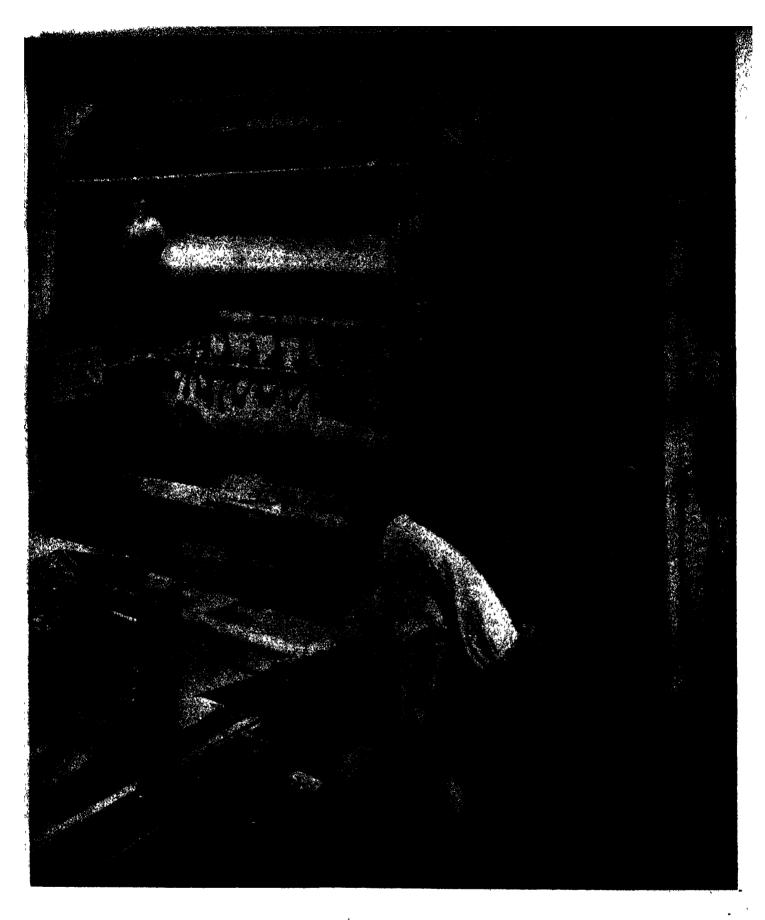

SIR RICHARD GREGORY

upon Sir Richard are the doctorates of science of the Universities of Leeds and Bristol, and doctor of laws of the University of St Andrews In 1933 he was elected a Fellow of the Royal Society of London under a special statute reserved for those who "either have rendered conspicuous service to the cause of science, or are such that their election would be of benefit to the Society" Only ten other living Fellows of the Royal Society, including prime ministers and peers of the realm, were elected under this statute.

His view is that the main mission of science is to cultivate a habit of mind which may be usefully presented to many problems of modern life. "When scientific work is instituted solely with the purpose of securing commercial gain," he says in his book "Discovery," "its correlative is selfishness; when it is confined to the path of a narrow specialization, it leads to arrogance; and when its purpose is materialistic domination, without regard to the spiritual needs of humanity, it is a social danger and may

become an excuse for learned barbarity."

Sir Richard's early contacts with social reformers and with the stern realities of life and labor made him familiar with the human aspects of applied science as affecting industry. This probably accounts for the attention given to the social relationships of science during his editorship of Nature, which is recognized as the leading organ of the professional scientific world. Its attitude toward social matters is that, as science is responsible for the industrial developments and economic changes which have caused violent disturbances in the social structure, and has provided also the means by which civilization may commit suicide, it has a duty to guide the human race to the wise use of the powers it has created Su Richard is regarded as the leader among British representatives of science, especially in the younger generation, in the promotion of closer relationship between science and social problems and the progress and use of scientific knowledge in the service of the world of man.

ACCURATE MACHINERY FOR BETTER TIRES

THIS huge machine, operating with a high degree of accuracy, is used in one step of the process of making the safe and efficient tires on which modern motor cars roll. It performs a calendering operation by which rubber is sheeted out thin between steel rollers, preparatory to taking its place in the assembly of tires as described on page 158. It is machines such as this, applied in the production of modern needs, that have made possible economics which result in high-grade products at low cost.

Fire-walking in India, a typical scene such as is described in the article. Fire-walking is a world-wide ceremonial rite of purification a which the performers walk barefoot across pits filled with red-hot stones or glowing embers of wood, without injury to the skin of the fee

FIRE-WALKING

SURROUNDED with superstition and mystery for centuries has been the spectacular feat of walking barefoot over highly heated stones or white-hot embers without damage to the skin or flesh. In Polynesia and India, wizards and witch-doctors long have impressed and awed their peoples by these performances, which are undertaken after prolonged purifications and with ceremonial rite.

Innumerable times have Europeans and Americans witnessed these exhibitions, sent their observations to their home newspapers and attempted to explain, either as trickery or science, the obvious immunity of the participants. Their accounts make readable narrative but, with few exceptions, they have lacked what the scientist would call "exsential detail."

Scientists at last have investigated fire-walking and the secret seems to be solved. The solution is simple. The feat is stripped of its atmosphere of mystery and hoous poons. Probably you could do fire-walking sciently by doing it.

fire walking simply by doing it.

There are two sarieties of fire-walking on bested stones and on glowing em-

When Investigated by Scientists, the Oriental and South Sea Island Feat of Walking Barefoot on Fire or Red-hot Stones Gives up its Mysterious Secrets

By ALBERT G. INGALLS

bers—stone-walking and ember-walking.
Stone-walking is practiced in Polynesia—Fiji, the Cook Islands, the Society Islands, the Marquesas, the Hawaiian Islands—glamorous Pacific isles of romance. In a broad, usually circular pit of knee depth an immense wood fire is maintained for hours around stones about the size of a sofa cushion, till some of them are raised to red heat. The fire-priest, after going to all possible lengths to surround the occasion with magic and mysterious ceremony, walks barefoot over the highly heated stones. His feet are not even blistered.

Ember-walking is mainly East Indian in origin. It is, however, performed not alone in India but in other parts of the world where Indians have colonized—Trinidad, Natal, Mauritius, for example,

It is also performed in Japan. In a kneedepth, rectangular pit, perhaps six by twelve feet or even larger, many cords of wood are first burned. When the flames die down, and the large, deep bed of embers glows red-hot, the performer plods straight across it from end to end, barefoot and in no particular hurry. He reveals no pain and there are no dire results. Often he repeats the performance. Is it supernatural?

Anthropologists have long been familiar with fire-walking as a folk-custom. Frazer, in his "Golden Bough," and Andrew Lang in "Magic and Religion," landmarks in the literature of human folklore to which the anthropologist turns for reference in matters of cults and practices, describe the preparatory rites, the exorcism of the fire, the re-

ligious fervor, the fasts of the sorcerers, likewise the meaning of the ceremony to primitive man. Fire is an opponent of evil—of bad health, for example. The ghost, witch, warlock, wizard, or other hobgoblin of the imagination that causes the ill, dares not pursue the victim through the fire. Good logic, if you like its premises.

PROFESSOR Langley, of the Smith-sonian Institution and early airplane fame, witnessed a stone-walking ceremony in Raiatea, near Tabiti in the Society Islands. The pit measured 21 feet in length, was nine feet wide and kneedeep. Cords of wood were placed in it and on top of the wood about 200 rounded stones of porous basalt, weigh ing from 40 to 80 pounds each, were heaped in a mound. The wood was ignited and after four hours the inner stones were red-hot and bursting with loud reports. Four times the fire priest crossed the center of the pile of stones, barefoot, unharmed. Langley removed one hot stone on which the fire-walker had stepped and dropped it into a bucket of water. It boiled the water for 12 minutes: proof that the rock was a slow conductor of heat. A good conductor of heat would cool much more rapidly-also burn the fire-walker's fect, no doubt He brought the stone to Washington and reheated it to the same hue, thereby ascer taining the temperature to have been about 1200 degrees, Fahrenheit Lead melts at 621 degrees. Only recently have scientists made more exact experiments in connection with fire-walking than this simple one of Langley's.

Percival Lowell, the astronomer, wit nessed the ember-walking rite in Japan

A pit 12 to 18 feet long was filled with charcoal which was brought to a red-hot glow. Now the priest breathes in and out of his pursed-up lips-"a great purifier" After a few consecrated words he strides with dignified unconcern over the whole length of the fire-pit-barefoot. His exorcism of the fire has quite deprived it of its power to injure. Lowell, however, preferred to explain the immunity on more rational grounds—the toughness of the man's soles, the less sensitive nervous organism of the Oriental, and the exaltation and ecstasy of the performer, a combination of the physical, the physiological, and the psychological. Now that we have the approximate answer to the question, none of these three general explanations can be wholly excluded, but one of them comes out on top, quite definitely. In advance of the final answer, how would the reader rate the three?

A few years ago a reader of this magazine inquired whether an account of stone-walking in Tahiti, which he had read in Frederick O'Brien's "Mystic Isles of the South Seas," was really truthful or whether its author had not perhaps been under the spell of hypnotism when he witnessed the ceremony. This question was published and, as a result, eyewitness accounts of fire-walking in different corners of the earth have trickled in to the editor ever since. A reader from India, for example, offered this.

"I was an eye-witness to at least two fire-walking ceremonies and was indeed struck by the remarkable freedom from injuries which characterized the ritual At one of these which I saw at Pallavaram, in the Chingleput District, there were 18 men of ages from 18 to 65, who participated in the ritual. The fire was about 16 feet by 12 feet by 4 feet deep and was made up of huge logs of wood which were allowed to burn for over six hours before the men went into it barefoot and with only a wet loin cloth on their person.

"These men took a bath immediately before they got into the fire, and with the wet loin cloths on their person, freely walked over the red-hot embers, chanting some weird religious songs

"The only rational—at all events, what appeared to me to be rational—explanation was that these fire-walkers smeared their bodies with the juice of some leaves, which had the remarkable property of desensitizing the skin to fire. Other explanations ascribe the freedom from injury to mystic and occult powers, and to religious fervor in the walkers, which transcended all physical feelings.

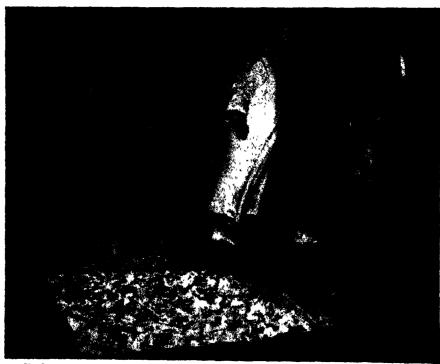

"In the second instance 55 men took part in the ceremony but only one was hurt. If the whole thing was a fake, how can we explain this observed fact of one man being injured?

"I honestly feel it is not a stunt, But, at the same time, I cannot for one moment reconcile myself to the idea that fervor, however deep, can save the victim from some bodily injury. It must therefore he some sort of anesthetic effect that is induced in the walkers by the previous application for some days or hours or even perhaps minutes, of some powerful juice which, while producing this effect, is not washed away by the bathing to which the walker subjects himself before the assembled audience -apparently to show them that they had nothing on their bodies to protect them from the fire.

"I would like that you invite a free expression of opinion on this matter from your readers over the globe."

IN Natal Province, Union of South Africa, are many East Indians, and another reader, F. Hawley Williams, of Pietermaritzburg, describes ember-walking as practiced there. "This ceremony," he writes, "is a religious penance ceremony and is carried out for the purpose of purifying the participants from sin, and to confer immunity from evil-doing in future. The candidates are required to undergo a preparation for at least ten days, during which time they are not allowed to eat meat, nor drink alcoholic liquor, nor come into contact with women. Each must bathe the whole body twice daily. Ceremonies are carried out every day at the temple and the candidates recite many prayers to their gods, prostrating themselves before the images. No drugs are administered and no treatment of the skin is given, but the majority of Indian workers do not wear boots and the soles of their feet become

"On the day of the final ceremony the

Kuda Bux, a Moslem magician from India, whose fire-walking tests are described in the text, after traversing barefoot the long fire-trench shown behind him

devotees are ceremonially bathed under the direction of a priest, in a nearby stream, while a crowd of women dressed in the sacred color—yellow—sing, dance, shout, and clap the hands, and youths play Indian musical instruments, the whole combining to make to European cars a hideous din. The devotees are next led to the temple grounds, preceded by an image of the goddess Mariamman carried on a platform on the shoulders of men, also by men beating tom-toms, playing wind instruments which produce a worse noise than bagpipes (with apologies to bagpipes), and clashing cymbals

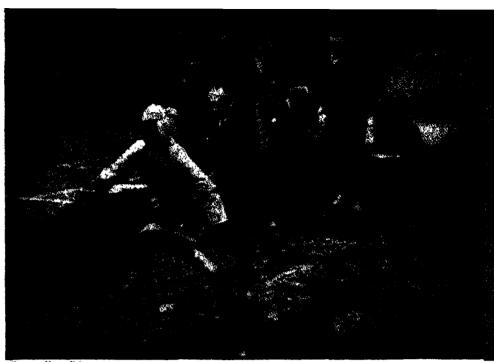

"On arrival at the gate of the temple grounds those taking part in the firewalking are in a state of religious frenzy, leaping, shouting, and pushing to obtain a front place in the path to the fire-pit. This year 15 men took part. Immediately before the first one crossed the burning eithers a goat was sacrificed by decapitation at the edge of the pit. This was about 30 feet in length, ten feet wide, and 18 inches deep and was a mass of hot wood embers, raked down fairly level.

"A PRIEST crossed the red-hot embers first, at an ordinary walking pace, followed by the devotees in two and threes. Some of them ran with long strides, others with short, sharp steps. A few completed only a part of the total distance and, their faith failing them, they ran to the side of the pit and scrambled out. The remainder completed the course, being assisted to reach the grass verge and to stand until the hysterical condition had passed off.

"No harm came to the participants.

"As the result of a long conversation with an expresident of the Hindu temple, Mr. J Sobiah, an educated Natalborn Indian, the writer feels that there is positively no trickery or faking connected with this ceremony, no preparation of the feet to harden the skin or in any way to cause the skin to resist the action of fire. Two Europeans submitted themselves to the ordeal, took the prescribed ten-day preparation, and one walked safely over the red-hot embers, the other having a small blister on one toe. What gives immunity from fire is not understood. The Hindus ascribe it to faith in their gods, coupled with the purification. One hears many theories advanced to account for the apparent loss of feeling-hypnosis, use of stultifying drugs, skin treatment and so on-but one must accept the word of men whose statements can be relied upon that, beyond purification, dieting, and prayer, nothing is done which can in any way account for the result. Faith is the great factor."

From Colorado another reader advances a hypothesis that is usually given consideration by most persons of scientific inclination while canvassing possible explanations for fire-walking immun-

Ahmed Hussam, another magician from India, walking across 12½ feet of red-hot embers at temperature of 1067 degrees, Fahrenheit, leading three Englishmen in their maiden fire-wa

ity A woman ironing, he suggests, will test the degree of heat by moistening the finger and touching the iron. The moisture on the finger creates a vapor cushion which protects it temporarily from being burned. Plumbers, he points out, are accustomed to direct the flow of molten lead with the bare palm of the hand, and here the same principle applies. Some moisture would be left on the body of the fire-walkers after the preliminary bath, he argues, since they probably do not use towels, and this would continue the supply of moisture after the first moisture of the bath had evaporated.

The phenomenon described is well known to scientists as the "spheroidal state of a liquid". The liquid, in drops (hence the word "spheroid"), floats on a layer of its own vapor and, though it does not itself reach boiling temperature, it rapidly evaporates from its exposed surface because of the adjacent heat. Water drops dancing on a hot stove give probably the most familiar illustration of the spheroidal state.

Unfortunately, two objections stand against this scientific phenomenon as an explanation of immunity in fire-walking First, it would be impracticable. It would be easier for a man to carry an armful of live eals the length of a day's walk than to try to make a wet loin-cloth feed a uniform supply of water down the legs to the soles of the two feet, even if no one were watching. Second, no fire-walker, unless he had temporarily lost his memory of the effects of the first attempt, would try this method a second time. The reason will appear later.

Richard Martin, of San Francisco, describes his observations: "I once saw a performance of fire-walking, and to my mind there is no mystery at all.

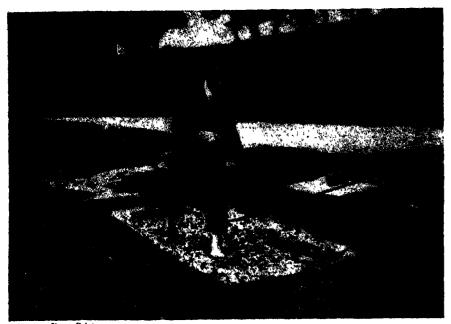

"The fire-walking took place in the South Pacific, in the island of Tahiti, It

was performed by a group of natives from the island of Raiatea. Hearing of the coming event, I questioned several of my native friends for an explanation. They all explained it upon superstitious grounds, which I did not believe, although I did not tell them so. I believed that the laws of nature could be the only explanation. I was convinced that if a native could perform it, then I could do likewise, in which I was partly wrong. I made up my mind to attempt to do all that the natives would do if nobody opposed me.

"The day of the fire-walking arrived, and I found that a pit had been dug, about 18 feet long, 12 feet wide, and three feet deep The bottom of this pit was covered with boulders about 12 or 14 inches in diameter, such as may be found in the bed of any of the streams. Upon these boulders a fire of logs was burning, with flames reaching about six feet high.

"THAT afternoon I returned to the location and found a crowd of people waiting. The fire had now been burning several hours, and was being allowed to burn itself out. The boulders were covered with red-hot coals, with low flames above them. The natives now placed the ends of long poles under the red-hot boulders, turning and prying them up, so that soon the red-hot coals were below the boulders. This caused the surface of the upper halves of the boulders to lose their redness, but the lower halves remained red.

"About six of the natives, clad only in a cotton cloth around their waists and reaching to their knees, now approached the pit in single file. The leader carried a bunch of long leaves in his hand. To natives, this kind of leaf has a superstitious meaning. Reaching the edge of

Reginald Adeock walking on a bed of embers having a surface temperature of 1472 degrees, Fahrenheit. The English tyro equalled the Orientals' best feats

the pit the leader stopped and, turning his face toward the sky, spoke in a loud voice about two dozen words in the native language. Next he stooped and, reaching into the pit, struck one of the boulders three times with the bunch of leaves. My native friends told me that all this was necessary to prevent the performers from being burned. Without hesitation the leader now calmly stepped with bare feet on the hot boulders in the pit and walked leisurely across its 18 feet, close ly followed by his associates. After crossing the pit they repeated their walk in the opposite direction. This concluded the performance

"AS SOON as the performers were out of the pit, I stepped to its edge, barefoot, to test the heating properties of a boulder, as I had previously planned to do. Extending one leg into the pit, I placed my bare foot heavily upon a boulder, then quickly removed it. I found the conditions just about as I had expected, Immediately I stepped upon the boulders and walked across the pit with bare feet. Then I repeated the walk in the opposite direction. Although I duplicated the performance of the native fire-walkers, I admit that I did not do it in quite such a leisurely manner; in fact, I walked rather fast, and for a very good reason! I then examined my feet and found them uninjured, although they did not feel as comfortable as could be desired. Within two minutes after walking on the stones, I repeated the performance, thus walking across the pit four times. This second walk was a mistake, because upon examining my feet again I found a blister the size of a 25-cent piece on one foot; also my feet were twice as uncomfortable as before. The boulders did feel very hot, as indeed they were, but they were not unbearable.

"The boulders used were of the kind that are characteristic of this group of volcanic islands. They have the same appearance as a rubber sponge and were undoubtedly at one time molten lava filled with bubbles of gas. This structure makes them ideal as poor conductors of heat. In addition, the performer has thickened skin on the soles of his feet."

The stone-walking variety of fire walking may permit as many as 25 steps. The stones are heated red hot but usually unevenly, because the flames do not play on them evenly, Professor Langley observed that the parts that were not redhot were nevertheless very hot. Even so, stone-walking is not usually so severe a test or so difficult a feat for the same distances as ember-walking, for here only a relative few steps may be taken with immunity Usually, also, the embers are hotter than the stones used in stone-walking. At least they are hotter than the portions of the stones that are stepped on, or else there are other differences

AND now we reach the London investigations, for the first time the active participation of physicists, and the solution.

The University of London Council for Psychical Investigation consists of ten members, four of whom are professors. Its Honorary Secretary is Harry Price and its Laboratory is at University College, in the heart of London.

A few years ago the Council decided to look into the question of fire-walking and authorized Harry Price to advertise for fire-walkers. Letters arrived from many who had seen fire-walking but none wanted to try it themselves! However, an (East) Indian magician, Kuda Bux, a Mohammedan, turned up and stated that he was a fire-walker. Tests were planned. The following is quoted from

one of two reports1 on experimental firewalks. "The object of the experiments," Harry Price states in his report-the first of the two-"was to ascertain if Kuda Bux was immune from burning when walking over the fire; if so, why? Is fire-walking based on trickery? Can anyone do it? Do the performers prepare then feet! Can they convey their alleged immunity to other persons? Do the walkers' prepare their feet with a paste made of alum, salt, soap, and soda, as has been alleged? Do they have to be in an ecstatic or exalted condition? Do they have to possess faith? Do they inject an ane-thetic into their feet? Do the wood ashes form an insulating layer on top of the fire, and thus prevent burning! Does the performer have to hurry along the trench, or can be stroll? Does he fast or otherwise prepare himself -mentally or physically-for the ordeal? Kuda Bux stated that his immunity from burns was due to faith. He also claimed he could convey his immunity to another and take him over the fire without in-

TRENCH one foot deep, three feet A TRENCH one took deep, three feet wide and 25 feet long was dug. Three tons of wood were laid in it and on the appointed day this was ignited. After an hour and a half, a load of charcoal was added, an idea of Harry Price's. in order to make a hotter, cleaner, and smoother surface. After three and a half hours from the beginning these fuels had burned to a glowing mass of red and black embers three inches deep. This was too shallow, but the researchers were unacquainted with fire-walking and in this and other ways on their first attempt to provide suitable conditions they did not quite attain the desired ideal. Kuda Bux said he preferred at least nine inches of embers. He could give no clear reason for this but alleged that it was much easier to walk on several layers of embers than on a thin layer of fire. However, he walked.

Before the test Kuda Bux's feet were examined by Dr. William Collier, of Oxford, who was present and pronounced his feet normal. Swabs were then taken and handed to a pathologist for analysis but nothing was found. One foot was then washed, evidently as a check or control on the other, in case of some substance having been applied.

Kuda Bux stood at the end of the trench and muttered a prayer from the Koran. He then stepped on the fire and took four steps, each foot making contact twice. He did not run, but walked (Please turn to page 173)

An Electrical Voice

Speech Created . . . Skilled Operation Requires Long Training Period . . . Result of Research

BUILT almost entirely of apparatus used in everyday telephone service, an electrical device which, under control of an operator at a keyboard, actually talks, is a development of Bell Telephone Laboratories. It was designed as a scientific novelty to make an educational exhibit for display at the San Francisco Exposition and at the World's Fair in New York.

The Voder, as the device is known, creates speech. It is the first machine in the world to do that. Individual vowels and consonants have been made by a variety of instruments, but they have never been linked into connected speech, Seated at a keyboard something like that of the oldfashioned parlor organ, an operator can carry on a conversation simply by pressing keys, singly or in combination. It takes a good deal of practice and some time to learn--not as much time as it takes the human to learn the mechanisms he is born with, but still quite a while. And it talks with what might be called a slight electrical accent. Nevertheless a skilled operator can make it -ay what she wants.

Designers of the Voder provided it with electrical equipment corresponding to the two kinds of speech sounds. One kind of sound is made by forcing the breath through the mouth, past tongue, teeth, and lips. Turbulence in the airstream sets up a hissing sound which contains a great many vibration-frequencies. Some of these are reinforced by resonances in the mouth cavity; that is the way in which are made all the sounds

Ten of the white keys each control a speech sound; the eleventh is for volume. The three black keys make the "stop" consonants. The wrist switch changes from consonants to vowels

of speech when one whispers, and such sounds as "s," 'th" and "f." In the Voder there is an electrical hiss, and with some of the keys the operator can control its quality so as to make those sounds. Other keys make the "stop" consonants like "d," "k," and "p."

Another kind of sound enters into human speech, most importantly in the vowels, like "a," "e" and "o." It comes from the vocal cords, and is very complex and somewhat musical. In the Voder, there is an

electrical source of sound corresponding to the vocal cords, and there is a pedal for changing its pitch and for giving to speech a rising or falling inflection as desired. When the operator wants the sounds made by the vocal cords, instead of whispered sounds or consonants, an arm rest switch is depressed. Then the particular parts of this vocalized sound which are wanted are selected by pressing the proper keys

THE source for this sound is the socalled "relaxation oscillator" which gives a saw-toothed wave in contrast to the smoothly rounded wave of a pure musical note. This saw-toothed wave has a fundamental note which gives the whole sound a definite pitch. Broad changes in this pitch mark the difference between male and female voices; gliding

change of pitch over a smaller range constitutes inflection. The Voder may be posed as a man or a woman by turning a knob, it may state a fact, ask a question, or emphasize a word according to the motion of its pedal.

When one talks, one shapes his mouth cavity so that some particular parts of the complex sound come through clearly while other parts are suppressed and unheard. This makes the difference between the vowel sounds. For the same purpose the Voder is provided with ten keys. Each of these controls the current in a definite frequency range.

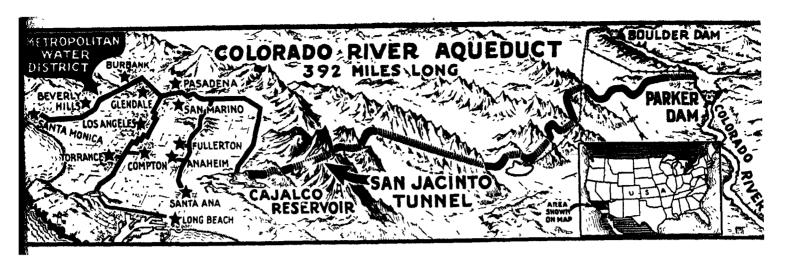

The Voder in operation. Foot pedal gives inflection to synthesized speech from loud-peaker

Source of current for each attenuator is an electrical filter which picks from the saw-tooth wave one particular group of its overtones. The Voder seems to speak most understandably when unimportant overtones are suppressed.

Considering all the keys, there are 23 different sounds available to the Voder operator. By combinations of keys she can mix these sounds and by the fingering she can control the shading. All speech sounds can be produced, but the number any operator can make use of depends on her finger dexterity; even granted the ability, only long practice will bring skill.

The Voder is an outgrowth of fundamental researches in telephony carried on in Bell Telephone Laboratories as part of this program, Homer W. Dudley, in the course of one of these researches, developed a speech synthesizer which could be controlled electrically by a speech analyzer. When the Bell System exhibits were projected for the Expositions at San Francisco and New York, the synthesizer part of the apparatus seemed to offer possibilities for development into a demonstration which would have educational value since through its use the formation of speech sounds could be shown. Mr. Dudley and R. R. Riesz thereupon constructed a model which has been put into form for exhibition by W. A. MacNair of the Laboratories' technical staff. Difficult tasks of working out its linguistic possibilities and a technique for its operation were undertaken by S. S. A. Watkins, who developed a course of training and instructed a corps of operators.

Boring Through a Rainstorm

HIRTY-SIX million gallons of water pouring down through the rocks of Mt. San Jacinto in Southern Cali forma every day ... Underground rainstorms which beat unceasingly against several hundred workers. . . . Solid tock. shifting rock, and unconsolidated rock which threatened constantly to fill the 13 2-mile tunnel being driven through those storms. Yet hard rock miners pressed ahead through the downpour, completing recently the dramatic job of boring the long hole through which even tually a billion gallons of water will flow on its 392-mile journey from the Colo-1ado river to Southern California

San Jacinto is one of 38 major tunnels on the Colorado River Aqueduct system. Totaling 108 miles in length, these have constituted one of the biggest tunneling jobs in construction history. Much of the 392-mile aqueduct system has been con-

San Jacinto Tunnel, Part of Colorado River Aqueduct System, Presented Engineering Difficulties . . . Rock and Water . . . Pioneer Tunnels Driven Ahead

By LYNN DAVIS SMITH
Metropolitan Water District

structed without strenuous opposition from the forces of nature, she seemed to concentrate most of her might at one point—Mt San Jacinto. This spectacular peak, which, with its foot in the desert only 400 feet above sea level, rises a sheer two miles into the air, is a fitting spot for a show-down fight between man and nature. For her principal weapon against man, nature chose the very thing that he will carry through that mountain—walt.

Water was encountered when sinking

both the Cabazon and Potrcio shafts from which the tunnel was to be bored Following several delays, construction was started on large-capacity pumping facilities at both shafts. These consisted of large bottle-shaped chambers cut out of the solid rock adjacent to the two shafts, Batteries of pumps having a total capacity of 29,600 gallons per minute at Cabazon and 17,400 gallons per minute at Potrcio were installed in these chambers.

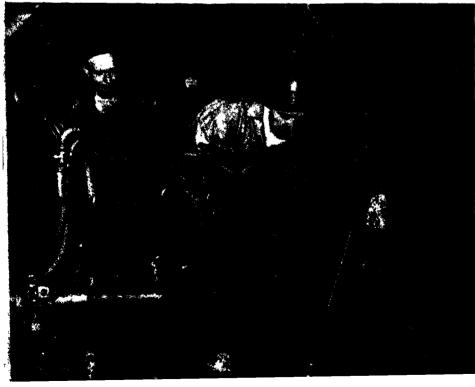

Auxiliary controls on the surface were provided so that the pumps, in their water-tight chambers, could be operated even though the tunnel should be completely flooded. Large steel pipe lines ran from these stations to the tunnel headings. The pumps continued to operate until Cabazon holed through to the east portal and Potrero holed through to the west portal, after which the water was carried through the tunnel and out at the portals.

WITH adequate pumping facilities installed, the hard-tockers once more turned their attention to driving headings. Work continued in the tunnel 24 hours a day, seven days a week, the two exceptions being Christmas and the Fourth of July.

Working in high-pressure water, four to eight men were needed to change drill steels. Holes at the bottom of the face had to be drilled under water. Sticks of dynamite had to be strapped to poles and the poles wedged into the drill holes so that the powder would stay in place long enough to be fired.

The greatest amount of water encoun-

'rotected against falling rock fragments by "hard-boiled" hats, and against water by ramous and boots, the drill workers pushed ahead in the hard rock through which water poured

tered at a working face was in East Potrero, where it once reached a peak of 15,800 gallons per minute. Oddly enough, as though the old man of the mountain had found that even this didn't stop the crews, the heading almost immediately advanced into a dry section. So decided was this change that the front of the drill jumbo was completely dry, while the back end was being doused with 10,000 gallons of water per minute

For the purpose of reducing the length of time required to excavate the tunnel, an additional access point was constructed. This is known as the Lawrence adit, and is located approximately midway between the Cabazon and Potrero shafts.

This adit, which is a mile long, is built on a 25 percent grade, and drops 1324 feet from its portal to its intersection with the line of the main tunnel. The adit was completed three months ahead of schedule, and headings were immediately started east toward Cabazon and west toward Potrero

About the time that construction of the Lawrence adit was started, both the Cabazon and Potrero headings were in heavy going. The engineers then decided to use proneer tunnels paralleling the main tunnel. These pioneers are 10 feet square and were driven south of and parallel to the main headings, which, by this time, had both been angled north to intersect the Lawrence adit. In bad ground, these pioneers immediately proved their advantage. Being smaller, they were driven faster and thus were able to get considerably ahead of the main headings. This made it possible to explore the ground in advance and also to shoot cross drifts over to the line of the main tunnel, from which new headings could be put into operation.

WHEN the main heading at Cabazon had crossed all known major faults between Cabazon and Lawrence, and the Potrero main heading was able to keep pace with its pioneer, it was possible to suspend pioneer operations, although all equipment was still maintained, ready for immediate use should heavy water flows or broken ground again make its use advantageous.

Throughout the course of work on the San Jacinto Tunnel, the engineers were constantly confronted with problems that affected every man on the job and which had to be solved quickly and efficiently before the fight against nature could be carried on.

Today, with rock-moving in the tunnel completed, it is impossible for the average visitor—unless he himself is a tunnel man—to realize the tremendous odds that have been overcome in this battle against the mountain. As he speeds along on the tunnel train, mile after mile, his principal impression is of the seemingly unending length of the bore. The scars of battle have largely been covered

A common sight during the boring of the San Jacinto tunnel was a downpour of water such this. At one time the inflow to the tunnel at the working face was 15,800 gallons per minu

over, for more than seven miles of the tunnel have already been lined with concrete and completed.

His guide may stop the train in an unlined section and point out giant timbers, 16 inches square and standing together "skin tight." Here a few months, or a few years, ago the heading was brought to a standstill—for a day or for weeks—while the hard-rockers battled water and heavy ground. Ground so heavy that it crushed huge timbers as though they were matchwood, and bent and twisted heavy steel ribs into grotesque shapes. It required the heaviest timbers available, standing together as tight as they would go, to hold the mountain in its place at such points

and keep the tunnel clear of debris.

A little farther along, the train may stop in a section where the visitor is told that this is good ground, and here the face was advanced 40 feet in a single day. Here the gray granite stands clean and unsupported, and the crews drove "full face" with eleven drills working on the heading at one time. Eleven drills working in a solid rock chamber, 18 feet square, and each drill making more noise than a machine gun!

But those noises are silenced now. Drills no longer sputter and rattle. The big bore is finished except for lining with concrete. Another few months will see it ready to receive water.

As Astronomers Meet

CCIENTIFIC societies are sometimes criticized for devoting their attention to one narrow field. but anyone who listened to such a list of papers as were presented before the recent meeting of the American Astronomical Society in New York could hardly repeat this charge. Half the range of human knowledge seemed to be represented from the utmost limits of the Milky Way to the internal structure of atoms, from simple - and beautiful - photographs showing the stars in their natural colors, to the intricacies of mathematical theory, from a star 100,000 times as bright as the Sun to the feeble flash of meteors ---vet all had a direct connection with the science.

Beginning "at home," we may note an interesting report by Dr. Wooland of the Weather Bureau on the influences which modify climate. If the Earth's surface, like the Moon's, had practically no pow er of storing up the Sun's heat, the longest day of Summer would be the hottest, and every night cold Also the South Pole in its midsummer would be the hottest place in the world. Storage of heat, mainly in the ocean waters, modifies this profoundly. In the deserts along the Mexican border, the hottest temperature of the year comes, on the average, ten days after the summer solstice; on the California coast near San Francisco the year's hottest weather comes three months later! A hundred miles inland, the lag is very much less. When the great major seasonal variations are so profoundly influenced by local conditions, it is no wonder that the minute and barely measurable changes in solar radiation connected with the sunspot cycle have no practically perceptible effects

Next in order of distance should come Whipple's studies of meteors from photographs taken at Harvard. If one turns a camera on the stars for an hour or two there is not one chance in a hundred that a meteor bright enough to record its passage will flash across the field of view. But when the stars are systematically being photographed for other purposes, two cameras, at Cambridge and Oak Ridge, 25 miles apart, can be pointed at the same part of the sky-or more precisely, toward a point 50 miles or so up in the air, at the level where meteors appear. Once in a while a meteor will be caught and the converging lines drawn from the two stations to points upon its path suffice for an accurate survey of its position in space

Moreover, by arranging a narrow re-

Among Themselves Astronomers Specialize On a Wide Variety of Problems, and Then Meet Twice Yearly to Tell Each Other About Their Researches

By HENRY NORRIS RUSSELL, Ph.D.

Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Mount Wilson Observatory of the Carnegie Institution of Washington

volving shutter which cuts off the light for an instant 20 times every second the speed of the meteor on its path can also be found. Four meteors recently ob served, whose lines of flight, when they met the Earth, were almost parallel in direction, were thus found to have al most exactly the same speed, relatively to the Sun, and to have been moving in orbits of nearly the same size and shape, similar to those of short period comets It is, of course, no news that meteor swarms of this kind exist; but the observation of individual meteors with such precision that their orbits may be accurately calculated is something new, and opens up an important line of regular work for the future. In particular, if the orbits of meteors belonging to our solar system can be calculated accurately, it will be possible to be quite certain in other cases that meteors have come in from interstellar space. Little clear evidence of such invaders has yet been secured, but more may be anticipated as the work goes on

LARGE-SCALE photographs of the Moon, showing very fine detail. were described by Burns of the Allegheny Observatory, and color-photographs of the recent lunar eclipse by Stokley and by Hoffman, A more unusual observation dealing with the Moon comes from Mount Wilson, When a star disappears in occultation, it vanishes instantaneously, so far as the eye can see-that is, within not much more than a tenth of a second. Now the Moon's motion in the sky is about half a second of arc in a second of time, or 0".05 in a tenth of a second. Even a huge star like Antares, with an angular diameter of 0".04, would disappear in one twelfth of a second. But modern electrical recording devices can observe far more rapid changes. Putting a sensitive photocell at the focus of the 100. inch telescope, and connecting it by a series of amplifiers with a device recording on a rapidly moving film, Whitford has found that the disappearance of the

3rd magnitude star \(\beta \) Capricorni was by no means instantaneous, but took more than a hundredth of a second. The changes in light look at first sight very strange --- a slight drop, a rise a little above normal, and then a rapid and deep fall to disappearance. But this, too, was anticipated. Since light consists of waves, the shadow of a clean-cut straightedge is not perfectly sharp but is bordered on the outside by faint diffraction fringes, while inside the geometrical hmit the light falls off gradually. This has been a familiar laboratory experiment for a century—the fringes being so narrow that they require a magnifier to observe them But with the shadowcasting edge at the Moon's distance, the width of the first bright fringe is about 60 feet, and, as the shadow is carried by the Moon's motion, this will take about one fiftieth of a second to pass over the observing telescope. The exact calculation of the changes of light is complicated, since the observing cell is sensitive to light of very different wavelengths, whose effect must be separately computed and added. When this was done the observed curve agreed very closely with the calculated. If the star itself has a perceptible diameter, the shape of the curve will be somewhat changed; and there is hope that, in this way, star-diameters too small to reach in any other way may be measured.

One might suppose that when the occultation was almost a grazing one, and the star disappeared obliquely behind the Moon's limb, the time-scale would be drawn out and the observations increased in precision. This would happen if the Moon's surface was smooth; but the effective part of the Moon's edge, at a given moment, is not more than a quarter of a mile long, and the surface is so rough that this might be inclined at almost any angle.

Our nearest planetary neighbor, Venus, was the subject of a noteworthy paper by E. C. Slipher of the Lowell Observatory—the most experienced photographic observer of the planets. At

rote pats

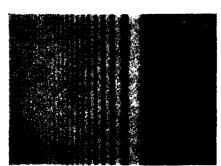

her conjunction last November Venus was only 3 degrees from the Sun. In this position the planet's atmosphere, illuminated by the Sun's light coming from almost directly behind, can be seen as a luminous ring, completely surrounding the disk. This, again, is not a new thing; it was first seen by Rittenhouse in 1769, and has been observed several times since. But the ring phase has never been photographed before, nor seen when Venus was so far from the Sun. The clear Arizona air at the high altitude has probably something to do with this success; but only great observational skill could have succeeded in getting successful photographs with blue light as well as red, despite the foreground of intense light from our sky. The permanent record of this elusive phenomenon should increase our knowledge of Venus' atmosphere. Indeed, it already appears that the hazy layer in it which is lit up brightly enough to be seen in broad daylight was of variable depth from place to place and day to day.

VERY different side of planetary A study appeared in Brouwer's announcement of a new calculation of the orbits of Uranus and Neptune. Our present knowledge of the orbits of the planets, out to and including Saturn, is very accurate, but Neptune was discovered in 1846, and had been observed over little more than a quarter of its orbit when Newcomb calculated the existing tables of its motion. Any minute errors in the observations of this limited are would be greatly magnified in the predicted positions for the unobserved portion, and so it is no discredit to Newcomb's work that his tables now disagree by five seconds of aic with the observed position. Most of this discrepancy can be removed by small changes in the assumed size and shape of the orbit, without seriously affecting the agreement of calculation with the older observations. But to obtain tables which may be trusted for prediction as long as possible, it will be necessary to repeat the whole laborious calculation of the perturbations of Neptune by the attraction of the other planets-and also to revise the present tables of Uranus, which show smaller errors of the same sort. The very extensive calculations can be greatly shortened by the use of computing machines of the punched-card type, and the work will be done at the bureau recently established at Columbia University by the friendly co-operation of the manufacturer of these machines.

Solar problems were represented, among others, by Menzel's suggestion that the force which holds up the prominences may be radiation pressure, provided that the hydrogen lines in the extreme ulfra-violet (the Lyman series) are bright in the solar spectrum. (We

cannot test this directly, because the Earth's atmosphere is opaque to such light.) This may explain also why masses of hydrogen are observed to be driven away from the Sun at nearly constant speed, despite the powerful pull of gravitation.

Coming to the stars, a series of papers by several authors may be noted, dealing with eclipsing variables. By careful ob-

As Professor Russell mentions in his article, diffraction patterns usually are so fine as to require magnification to be seen Here, however, is a diffraction puttern made with a straight-edge and much larger than is common. It was photographed by Prof. Mason E Hufford, of Indiana University, under arrangements comparable with those in which the Moon is the straight-edge: The lightsource (monochromatic) was 110 feet and the straight-edge 55 feet from the plate. The result was as many as 40 dark fringes visible on the original plate. (The fine mesh pattern on the illustration is an extraneous feature due to reproducing one half-tone from another half-tone —in this case from the one published in The Journal of the Optical Society of America, December, 1937, from which the photograph is taken and in which other photographs of broad diffraction bands are shown)

servation of stars of this sort we can find out many things which can not be determined otherwise.

For example, when the stars of a pair are close together, they are pulled out by their mutual attraction into egg-shaped forms, with their long ends pointing toward one another. When these bodies are seen broadside on, half way between eclipses, the total light is naturally greater than when they appear nearly end on, just outside eclipse. From accurate photometric observations, we may find the amount of this ellipticity. But theory shows that the shape produced by the tidal forces will depend not only on the sizes, masses, and distance apart of the stars, but on the distribution of density inside them. A star with the material greatly concentrated toward the center will be less elliptical-other things being equal-than a homogeneous mass. Calculations on this basis indicate that the increase of density toward the center is small. But another effect of the elliptical form is that, if the orbit is eccentric, the point of closest approach of the stars will gradually move forward along the orbit. Sterne, of Harvard, from an extensive discussion of the rather complicated theory, finds that, for the two stars of this sort which have so far been fully observed, the density at the center must be about 50 times the mean density.

A way out of the discordance appears in a note by the present writer. The theory of the e-cape of radiation from a star indicates that, on an egg-shaped star, the surface should be brightest at the points nearest the center-where the force of gravity is greatest-and least at the ends. When we see the star end-on, the less luminous portions fill most of the visible disk: when it is side-on, the brighter parts do so, thus increasing the range of variation. Allowance for this, and also for the fact that, like the Sun, the star's disk should appear brighter at the center than at the edge, removes the discrepancy

Kopal, of Prague-now working at Harvard--pointed out that, in some eclipsing pairs, the observed ellipticity effect is smaller than might be expected, and explained this on the very reasonable assumption that one star of the pair had "broken away from the tidal control of the other, and was rotating more rapidly-- in which case, though flattened at the poles, it would not be egg-shaped." Hall, of Amherst, presented observations of our old friend Algol--in the infra-red with modern plates -showing that the loss of light at the principal eclipse, when the small hot star is partially eclipsed by its companion, was less, and that at the other eclipse greater, than for visual light -which adds confirmation to the proof that the companion is redder, and therefore cooler, than the primary.

Mcl.AUGHLIN reported from Michigan on the remarkable star Upsilon Sagittarii. From the peculiarities of its spectrum, which is like that of the supergiant Alpha Cygni, but much "more so", it has long been suspected that this is a very bright object. The interstellar calcium lines in its spectrum are very strong and from this McLaughlin estimates that the distance is 2000 parsecs—6500 light-years, and the absolute magnitude —7, or about 60.000 times the brightness of the Sun, and comparable with the brightness tars in the Magellanic Clouds.

Shapley, from the Harvard studies of faint variable stars, has found evidence that there are scattered stars extending to a distance of at least 35,000 light-years on each side of the plane of the Milky Way. Though so remote they belong to our system.

Though incomplete, this sketch of what the astronomers told one another in two days' meetings may give some idea of the present activity, and of its varied range.—Princeton University, January 5, 1939.

Pollution Kills Fish

POLLUTION in streams tends to increase with population. New and expanding industries produce an irregular but progressive pollution invasion of once clean streams, while an increasing number of people seek recreation in sports fishing in National, State, and local parks and torests and on private estates and properties, and commercial fishermen continue their age old efforts to obtain a "catch"

The problem of stream pollution is, therefore, of direct concern to those who gain a livelihood in the fisheries industries, to consumers of shellfish and fin fish, and to those who at intervals fortily their health and strength with recreational fishing

The value of the catch of 40 species of edible fish, as reported by the U/S Bureau of Fisheries in 1934, was \$70,905,000. About 73 percent of this income was derived from species of fish that may be subject in greater or less extent to the effects of coastal pollution.

In the vicinity of large cities which discharge sewage into tidal estuaries, the damage is greatest. For example, near New York City approximately 105,000 acres of productive shellfish areas have been closed, including Raritan, Jamaica, and Newark Bays, Kill Van Kull, Arthur Kill, East River, Harlem River, Hudson River as far as Yonkers, and portions of Long Island Sound beyond the Connecticut line. Near Norfolk, Virginia, approximately 38,400 acres, including all of Hampton Roads, have been closed. Some of the areas are valued at several hundred dollars per acre. The cities of Providence, Rhode Island, and Baltimore, Maryland, located near important shellfish growing areas, have spent large sums for sewage treatment works. Where the river carrying the sewage flows relatively long distances before it reaches the tidal estuary, as in the case of Philadelphia and Washington, D. C. less damage is done from the standpoint of destroying shellfish beds because the river has a chance to purify itself before it reaches the shellfish growing areas.

INDUSTRIAL wastes, on the other hand, sometimes objectionable in high dilutions and difficult to treat, may remain potent over long periods of time and may affect both aquatic life and domestic water supplies at relatively long distances from the source of pollution.

While this subject is only one phase of the broad problem of water pollution,

Industrial Wastes, Sewage, Mine Waters Pollute Rivers, Harbors... Fin Fish, Shellfish Seriously Affected... Research Needed To Correct Evil

By L. M. FISHER

Senior Sanitary Engineer U S Public Health Service Interstate Sanitary District No 2 Washington D C

it is important, since it deals with a ditect effect on public health in that shell fish have been involved more or less frequently in the spread of disease. It deals with an indirect effect on public health in that trade wastes and sewage tend to make certain valuable sea foods scarcer and more expensive, thus depriving a portion of the population of the benefits of foods rich in iodine, iron, copper, and other essential food elements and vitamins.

Among the causes of the progressive but irregular increase in pollution of streams by industrial wastes are the reestablishment of the fermentation industries discharging exhausted mash, the sudden growth of the cellulose textile industry with its spent chemical wastes, the development of the mid-continental oil fields, and the gradual extension of mining, the latter industry contributing vast quantities of dilute sulfuric acid produced by the action of air and water on exposed sulfur compounds in the mines

Twenty years ago, all the tributaries of the Ohio River, with the single exception of the Monongahela, were alkaline Now the Allegheny in Pennsylvania, an I many of the streams in West Virginia are acid most of the time, and the acid line in the Ohio River is being extended farther down each year, although the mine-sealing operations recently under taken give promise of retarding this encroachment Another invasion by tradewaste pollution may be expected in southern streams and coastal waters as a result of the recently developed process for manufacturing paper pulp from slash pine, resulting in the discharge of chemical wastes and paper fiber into our

While water is being polluted by trade wastes throughout the whole country, the

Countery Conservation Department, State of New York

A sample of what stream pollution can do and often does. Millions of fish, some of
them quite large, were destroyed in the Niagara River from this cause in one year

'rote oats

Entrances to abandoned coal mines scaled to exclude an and thus prevent formation of sulfuric acid which has seeped into nearby rivers and acidified them

problem is more acute, generally speaking, in the section north of the Ohio and Potomac Rivers and east of the Mississippi River which contains 65 percent of the total urban population.

Sewage and industrial wastes affect shellfish and fin fish directly in one or more of several ways. They may decrease the oxygen content of the water to a point below which fish life cannot be sustained (usually stated to be about 2 parts of oxygen to a million parts of water). They may destroy fish by increasing the acidity, alkalmity, or salt content of the water, or by introducing poisonous substances; or they may increase the turbidity so as to exclude light and prevent the growth of food. Again, they may deposit a blanket of fibers and waste material on the bottom of the stream so as to destroy the fish food found there. Some wastes impart disagreeable or repulsive odors or flavors to fish or shellhsh, and others produce unnatural discoloration which makes the fish objectionable to would-be consumers.

THE most frequent offenders in decreasing the oxygen content of wa ters are domestic sewages and those industrial wastes containing large quantities of organic matter, such as the scouring water and milk wastes from dairies; blood and offal from packing plants; blood and offal from packing plants; hulls, vegetable pulp, and wash water from canning plants and beet sugar plants; spent mash from breweries and distilleries; sawdust from sawmills; wool scourings, grease, and dyes from textile plants.

The polluting material which reaches our streams in the greatest volume, and which is detrimental to fish over the largest stream-bed area, is probably acid mine wastes coming principally from

coal mines. There are thousands of mines, both active and abandoned, discharging acid drainage which in the aggregate amounts to thousands of tons of concentrated sulfuric acid daily. A considerable reduction in acid from abandoned mines has been effected in recent years by a WPA mine-sealing project sponsored by various state health departments.

Discharge of sewage into our streams or coastal waters, in addition to decreasing the oxygen content of the water, may result in forming sludge deposits on the bottom, and films of grease and scum on the surface, which tend to interfere with the absorption of oxygen from the air and to destroy small forms of aquatic life. Not infrequently, sewage contains industrial wastes and poisons, discharged either by design or accident Such substances may cause great destruction to fish life—as occurred at Buffalo, New York, in November and December, 1937, when hundreds of tons of fish, valued at more than a million and a half dollars, were killed by the discharge of poisonous industrial wastes.

Municipal sewage frequently contains oil from garages and industries-in some instances in sufficient amount to interfere with fish life. In coastal waters the principal sources of oil are probably the bilge water of vessels, leaks in oil storage tanks, refineries, and uncontrolled oil wells. The oil has a two-fold effect on oysters and other shellfish. It retards and interferes with the propagation of diatoms, which constitute the principal diet of many mollusks; and it reduces the rate of feeding by exerting a narcotizing effect on the feeding mechanism. The water-soluble substances impart an oily flavor to the meat, rendering sea food from oil-polluted water unsalable. It also destroys fish spawn and fiv.

When domestic sewage reaches shellfish-growing areas in sufficient concen trations and freshness, it may contami nate the bivalves with disease-producing organisms. In numerous instances, shell fish so contaminated have been held responsible for the spread of disease. The most recent large epidemic of this type m the United States occurred in the winter of 1924-1925, when several hundred cases of typhoid fever in Chicago, New York, and other cities were ascribed to contaminated oysters. The wide publicity given this outbreak destroyed the market for shellfish overnight, and the Public Health Service was requested to assist in restoring public confidence in the safety of shellfish as a food. As a result of this request, the Public Health Service formulated minimum requirements for the sanitation of the shellfish industry. The various states have adopted regulations at least equal to the minimum requirements, and issue certificates good for one season only to shellfish dealers who comply with the standards. These certificates are listed by the Public Health Service as long as it has confidence in the effectiveness of the contiol measures of the various states, and copies of the list are supplied to state and local health authorities throughout the country. Municipal health authorities are usually quick to exclude from their markets shellfish not obtained from shippers on the lists of the Public Health Service. This plan has been in operation for 12 years and has provided effective control

SHELLFISH grow extensively only in protected coastal waters receiving the runoff from large rivers. These areas are definitely limited; they cannot be appreciably increased or extended. Hence, the character of the wastes discharged into streams tributary to them is of great importance. A number of these areas are now so contaminated with domestic sewage that shellfish cannot be marketed from them directly. Their existence is a constant threat to the health of consumers in our coastal states because of the surreptitious taking of shellfish from them by individual poachers.

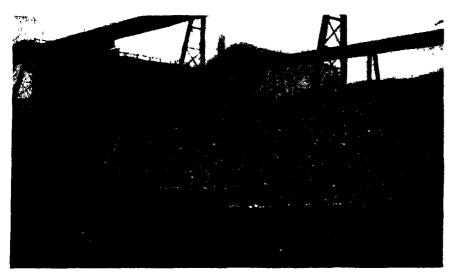

Fiber wastes and chemical wastes constitute the chief sources of pollution from pulp mills. The fibers eventually deposit on the bottom of streams a blanket of imponderable material which stops the normal growth of plant and animal life.

Mercaptans, which are sulfur ethers, or alcohols, found in the cooking process in sulfate pulping operations, have a very disagreeable odor and have been found poisonous to fish in concentrations as low as one part per million. They impair the nervous system of fish so that death eventually results.

The waste liquor from sulfite processes quite readily combines with the dissolved oxygen in the stream into which it is discharged. It also has an acidifying effect on the water and may introduce compounds of a poisonous character, such as the lignin salts.

Several detailed studies of the effects of pulp mill wastes on oysters have been made--among them one in Puget Sound pulp mill waste in the water is the cause of the failure of oysters to grow and fatten in the upper part of the river and that the elimination of pulp mill pollution is a prerequisite for the restoration of the oyster industry in the York River."

At present the paper industry is engaged in studies to discover useful byproducts which can be made from pulp

Symbolic of our great shellfish industry, a pile of oyster shells. Already a number of large oyster beds have been abandoned because of water pollution

at Oakland Bay, Washington, and another on the York River in Virginia.

In the Puget Sound study, it was found that sulfite liquor, when added to sea water in concentrations of 0.5 to 10 parts per thousand, is decidedly unfavorable to oysters, and in the laboratory produced death in from 2 to 29 days, depending upon the concentration. The report that followed the investigation recommended that pulp mills using the sulfite process should totally exclude their waste higher from waters in which oysters are grown

ON the York River, Virginia, the ov-ster industry has been declining markedly during the past two decades, according to reports, but it was not until 1935 that sufficient funds were available to establish a field laboratory to make systematic ecological observations and physiological experiments. The results indicate the existence of an environment in the upper part of the York River that is decidedly harmful to oysters, and physiological experiments yield direct evidence of the harmful effects of pulpmill effluent, reducing both the number of hours of feeding and the rate. Oysters taken from polluted areas in the York River and planted in clean waters improved markedly; glycogen content, which fairly expresses the quality of the meat, increased to normal levels Shells were strengthened by deposition of lime, and growth was resumed.

The conclusion is reached by the Bureau of Fisheries that "the presence of mill wastes, as well as methods which can be economically employed to keep objectionable wastes from streams. As a result of this research, sulfite waste liquor may eventually become an important chemical raw material, and some progress in reducing the quantity and destructiveness of sulfate wastes is apparently also being made.

Of the sulfite waste liquor, 65 percent is fermentable. Bakers' yeast is prepared by neutralizing the waste liquor, moculating it with yeast, and allowing this to grow under carefully controlled conditions. Approximately 20,000 pounds per week are being produced at one plant in Nova Scotia, and equipment to double the output has been installed

In Washington, one pulp and paper mill sprays the waste liquor down a stack 120 feet high, concentrating it to about 50 percent solids, and sells the product as a binder for secondary roads. Concentrated sulfite liquor also has some uses as an adhesive and forms the base for most of the linoleum cements on the market. It also can be burned in a manner similar to fuel oil, but while this is practical from the viewpoint of pollution prevention, it is inefficient from the viewpoint of chemical utilization Other products, such as tanning extracts, phenol, vanillin, and fertilizer material can be obtained by precipitation methods, it is reported.

Industry is essential to the continued existence of modern civilization Without industry, present standards of living could not be maintained. Practically all

our wealth, as represented by goods, is produced by industry. However, those industries which provide food to sustain life are basic and must exist before the production of goods can be undertaken. Because of this it seems reasonable that we should be interested in taking such steps as may be necessary to safeguard a natural food resource, responsible for producing such an important item in our food supply as fish and shellfish; and further it seems logical to conclude that no private industry should be permitted to damage or destroy another existing industry by the discharge of harmful wastes. The principal cost of carrying on research work to discover profitable methods for utilizing wastes or economical methods for disposing of them harmlessly should fall upon the industry responsible for their production It should be recognized, however, that there is a large public in terest involved

RESFARCH laboratories adequately financed with public funds should be able to evolve methods for recovering profitable by-products. Patent rights could then be issued to the government. making the processes available to all without the payment of royalties. It is conceivable that in this way sufficient returns to the public might accrue to repay fully the expenditure Money spent for such work should not be considered as just another form of government spending, but as an investment for the welfare of the people, who benefit from a judicious use of the country's resources. The principal source of public funds for studying such a research problem should, perhaps, be the industries themselves, but their contributions should be supplemented by other public funds.

In all fairness, the issuing of summary orders to effect abatement of stream pollution should be limited, for the time being, to those industries for the treatment of whose wastes feasible methods are now available. Also, all units of a given industry, regardless of their location, should be required to effect abatements simultaneously, so that no single plant or group of plants would enjoy an advantage over competitors. Such a program calls for federal participation.

To anyone who has noted the increased demands of the public in recent years for the effective cleaning of streams and coastal waters, it must be apparent that the time is rapidly approaching when an intelligent and comprehensive plan for dealing with the problem must be evolved. If industry and government co-operate in finding a solution, it will be easier, less costly, and less disruptive than if a thoroughly aroused public, irked by delays and subterfuge, finally insists on immediate, drastic, and precipitate action.

Rubber Saves Trees

MODERN tree surgeons are learning more toward use of materials of a highly resistant nature which will give with the tree's motions, will not harm the tender growing cells by chafing, and will at the same time permit the growth of an even, natural roll or callousing of the cambium layer over the filling Rubber has been found to be the most satisfactory material to meet these exacting requirements. Of over 5000 cavities that have been filled with rubber, formed in special interlocking strips, not one has failed and all have healed rapidly. Consequently, the use of rubber is spreading

Fitting an end of a strip The concave upper and convex lower sides interlock all strips in a cavity. The "T" on the rear of the strip ties in with the cavity-filling compound

After a cavity is cleaned and dressed with tar, sections of the specially compounded rubber strips, cut to proper length, are wedged into the clean opening

Fitting a section of a more recently designed strip. On the rear face of this there is only a single channel to interlock with the filler. Rubber may, of course, be used in filling tree cavities in any weather, thus giving it a big advantage over other materials

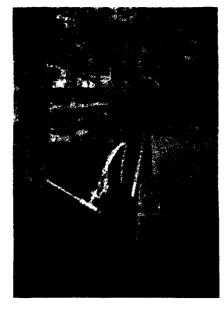

After the strips are wedged in tightly, a motor-driven buffer rapidly takes away the slightly projecting edges of the strips and leaves a smooth, natural looking surface

A filled tree is sightly and in some cases its wounds are scarcely noticeable. Nature soon completes repairs with healthy growth

The special, new machine which forces melted, sterilized wax, by steam pressure, into the cavity back of the rubber dam. Rubber and wax effectively exclude water, bacteria, and fungus and let the tree heal

Section through a cavity showing how this process, developed by Goodrich research men and Van Yahres Tree Service, permits rolling growth of new wood over the cavity

THERE is no need for any remarkable machine, the brain-child of some science-fiction author, to enable us to peer into the fourth dimension.

But is there any fourth dimension into which to peer? Or, if there is, isn't time the fourth dimension, and how can one peer into time?

Time is sometimes treated mathematically as something like a fourth dimension, but time is "imaginary" in the mathematical sense of involving the square root of minus one. The fourth dimension which I am about to discuss is a fourth space dimension, exactly like the three—length, width, and height—with which we are all familiar, and standing at right angles to all three, just as each of them stands at right angles to the other two.

We need not agree as to whether or not such a fourth dimension actually exists, or even could exist. Being threedimensional creatures, we could not sense the existence of a fourth dimension, even if there were one. We are like the two-dimensional man of Dr. Edwin Abbott's story, "Flatland," who failed to

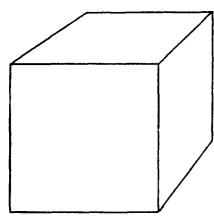

Figure 1. A cube in perspective

grasp the significance of "upward." But, by the use of the familiar principles of perspective, we can visualize exactly what hyperspace would look like, if there were such a thing as hyperspace

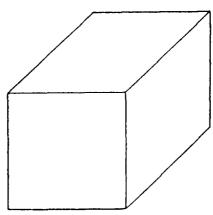

For, in much the same way by which perspective enables us to represent a cube on a sheet of paper, the same principles enable us to visualize the fourth dimension (if there is any) by means of three-dimensional figures.

The four-dimensional analogue of a cube is generally known as a "hypercube" or "tesseract." But the word "hypercube' includes objects of more than four dimensions, and so I prefer the word "tesseract," which applies specifically to a cube of only four dimensions. A five dimensional cube is called a "pentact." And so on.

Figure 1 shows the familiar two-dimensional picture of a cube. It clearly demonstrates how easy it is to give an accurate idea, in n-I dimensions, of what an object of n dimensions looks like

VISUALIZING

An Attempt to Peer Into the Fourth Dimension of Space by Constructing a Three-Dimensional Model or Analogy to be Used as a Taking-off Point

Ligure 2 Cube picture, isometric

There is another kind of perspective, known as "isometric," characterized by the fact that no distortion of lengths takes place. Figure 2 shows an isometric picture of a cube

By following the exact analogy of what we did to get Figure 2, we can make a three-dimensional model of a tesseract. Figure 3 is a sketch of such a model But this sketch, of course, involves using perspective twice in succession; it constitutes a two-dimensional picture of a three-dimensional model of a four-dimensional object—too far removed from the tesseract itself to convey a very clear idea of what a tesseract really looks like

We might just as well try to visualize a cube from a one dimensional representation of the cube. The two-dimensional

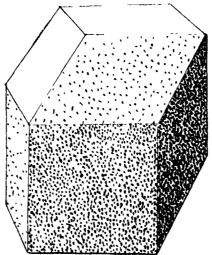

Figure 3: Model of a tesseract

picture of the cube (Figure 1 or Figure 2) gives us a pretty good idea of what a cube is like, but a one-dimensional representation (Figure 4) would be almost meaningless. Similarly, a three dimensional model of a tesseract would give us a very good idea of what a tesseract is like, whereas Figure 3 gives us no idea at all

So it is suggested that the reader build himself a cardboard model, by making an enlarged copy of Figure 5, cutting it out with shears along the outside border, bending it on the lines, and then pasting it together by the flaps. For convenience in pasting, I have key-numbered each of the flaps, and have given corresponding numbers to the edges to which the flaps are to be pasted.

Now, to digress for a moment in order to discuss the number of points, lines, and so on, in a tesseract, a pentact, and others, let us start with no dimensions: that is, a point. The one-dimensional analogue of a point is a line segment,

Figure 4. Almost meaningless!

obtained by moving the point a short distance into the added dimension. This motion gives us two terminal points and one line.

The two-dimensional analogue is a square, obtained by moving the line into the added dimension, a distance equal to its length. This motion doubles the number of terminal points, and produces four margin lines. The reason for this last number is as follows. The original line is one, this line in its new position in the new dimension is one more, and each of the two ends of the original line traces a line by its moving.

THE three-dimensional analogue is a cube, obtained by moving the square into the added dimension, the same distance as in each of the former shifts. This motion doubles the number of corner points, thus producing eight. The number of lines equals twice the original number of points: 12 in all. The number of surfaces equals twice the original number of surfaces, plus the original number of surfaces, plus the original number of lines: six in all.

Before proceeding to the tesseract, let

Hyperspace

By RALPH MILNE FARLEY, M.A.

TO many minds there is a strong fascination in the more uncommon, often bizarre aspects of mathematics, of which the geometry of hyperspace provides an example. From time to time such mathematical articles will be offered if the response to the present one indicates a sufficient volume of reader interest —The Editor

us tabulate these results obtained thus far.

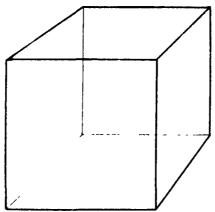

Object	Points	I mes	Squarec	Ciste
Point	1			
Line	2	ì		
Square	1	1	1	
Cube	8	12	6	- 1

An inspection of the above table shows us that (for the reason given under our discussion of the square) each number in any row is equal to the sum of twice the number directly above it, plus once the number diagonally above it to the left. This consideration enables us to compute readily the number of elements of a tesseract and of a pentact, thus extending our table as follows.

Object	l'oints i	Trues	Squares	Cutic	Tesser	
Cube	8	12	6	1		
Тевветас	t 16	32	24	8	1	
Pentact	32	80	80	40	10	1

By use of the same technique, this table can be extended indefinitely, to show the number of elements in hypercubes of higher order ¹

Let us now consider our pasteboard three-dimensional model of a tesseract Referring to Figure 2, we see that, in this pictorial representation of a cube, three of its six faces are invisible. They are within" (that is, behind) the three visi

Ligure 6 If a cube were transparent

ble faces Similarly, in the case of the cardboard model of the tesseract, 12 of its 24 faces are invisible, being "within" the 12 visible faces.

If, in Figure 2, we had represented a transparent cube (see Figure 6), then all six faces would have been visible. Similarly, if the reader will fasten 32 matches together with sealing-wax, to

'Algebraically expressed, the number of elements of order a in a hypercube of order b is 2^b b^t a! (b-a).' The sum of all the numbers in any row of the table is 3^b

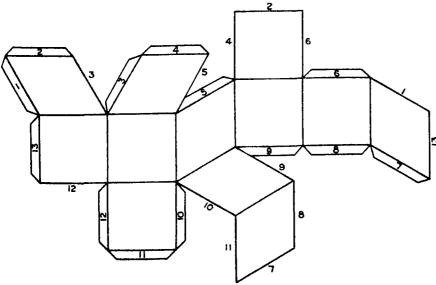

Figure 5. A reduced tesseract pattern. For convenience it may be enlarged

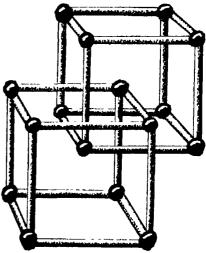

Figure 7 Building with matches

represent a projection of the 32 edges of a tesseract, he will be able to see all 24 faces of all eight cubes which go to make up this projection of a tesseract into three dimensional space.

To hitch these matches together, first form two cubes, with one corner interlocked, as shown in Figure 7. Then, using eight parallel matches set diagon

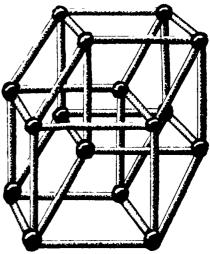

Figure 8: Contaming 32 matches

ally, run one of these eight matches from each corner of the first cube to the corresponding corner of the second cube, as shown in Figure 8.

As stated at the beginning of this article, I am here expressing no opinion as to whether a fourth space dimension does or does not exist. We three-dimensional humans are so three-dimension-conscious that we never can answer this question.

But the match-model of Figure 8 will enable us to visualize exactly what a four-dimensional cube would look like, if there were a fourth dimension and if we were permitted to peer into it.

Your Inferiority Complex—if you own one—is the subject of an article to appear in an early number.—The Editor

How Much Snow?

LAST winter, at 682 different locations in the Rockies and high Sierras, more than 30 000 exact measurements of snow depth and water content were taken, in order to estimate how much water the mountain snowhelds would supply in the run-off during summer months. To make this survey cost more than \$100,000. On it was predicated the expenditure, and saving, of nullions.

While the science of surveying snow is still in its infancy, its extent and iniportance are increasing rapidly Ridiculed at first in the last few years it has taken on world-wide aspects. To grasp its significance in our western states, picture a series of snow-covered mountain ranges that by their streams make life possible in dry intervening valleys. Abundant snow means abundant water Abundant water means power, and cheap electricity. More important still, it means abundant crops. Dearth of snowfall in the mountains means dry river beds in August, machinery standing idle, thirsty cattle and dying plants.

In states where rainfall is fairly constant the year around, extensive snow surveys are for the most part still unknown But in states where no rain falls from spring until late autumn, streamflow is the measure of life and prosperity. During years of drought the stream-flow, even in the mountains, sometimes drops to less than a third of normal. In extremely wet years it rises to three times normal.

Power companies build plants only where they can be assured of enough water, season after season, to turn their turbines. Western cities need to know, New Science of Snow Surveying... Quantity of Snow in the Mountains Determines Later Run-off Below ... Knowledge is Vital for Power Plants, Irrigation

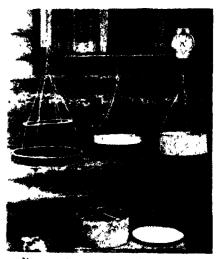

By MYRON M. STEARNS and BLAINE STUBBLEFIELD

far in advance, whether or not the water supply for their great aqueducts will meet their demands. Cattle men turn stock into valleys where they know grass will remain green and springs will not dry up Flood control and soil conservation districts alike need to know how much water they may expect. And even beyond that there are uses for snowknowledge for which few of us would even think how large the culverts should be under new highways across the Utah deserts, how deep the water will be in navigable rivers like the Sacramento in California, how far upstream salt tidal waters will force their way, making the current unfit for irrigating delta orchards.

TO make the snow survey, state federal, and private agencies join hands some of the work is supervised by the United States Forest Service, some by the National Park Service, some by power companies. Some is done by cities, by irrigation districts, by utility districts, by private land and lumber companies. California, like several other western states, has a state bureau of water resources. With a slender annual appropriation of \$15,000, the United States Bureau of Agricultural Engineering steps in and coordinates all the different

reports into a single survey for the entire mountain area from Mexico to the Canadian border and, with the co-operation of Canadian authorities, even beyond the boundary

In April, forceasts based on the snow surveys go on the main news-service wires. Newspapers print them in full. They are carried in radio broadcasts. Ranchers, hotel keepers, river men, orchardists, western salesmen of farm machinery, automobiles, and almost everything else, store keepers, dwellers along the great sand rivers of the

Evaporation pans used in snow surveying. Hanging. Tree pan, ice pan, and snow pan, Below. A core cutter for filling the snow pan, and a false bottom to raise the contained snow above the level of the melted snow

Southwest—all take note and build or

modify their plans accordingly.

To determine the stream flow of the great Colorado River into Boulder Dam snow surveys cover an area of more than 100 000 square miles along 330 miles of mountain crests.

In 1931 the residents of the Humboldt Basin were told that only 51 percent of the normal snowfall had been found at the source of their streams and that, owing to lack of spring rainfall, dry river beds and the like, they could expect barely 10 percent of the normal run-off:

Mt Rose Observatory, on the summit (10,800 feet) of Mt. Rose, in Nevada, where, in 1905, Prof J. E. Church established the first western snow surveying camp

no use of planting any late-maturing crops in the Humboldt Basin that year. (The Humboldt River rises in the mountains of Nevada, and was described by Mark Twain as being so small that the Forty-niners could run and jump across it for exercise, and then drink it dry to cool off. He might have added that in years of flood they could have sailed over the entire valley for a thousand miles.)

In 1934 the Utah Co-operative Snow Surveys forecast a severe drought in the Utah area. With this warning thus provided in time, diversion ditches were hastily dug to bring water from Bear Lake, on the Utah-Idaho border, to forestall a part of the shortage. It is esti-

The height of the snow sampler in the man's hands shows snow depth

mated that, through the timely snow surveys, a saving of nearly \$4,000,000 was effected. This is the first time in history that a drought conference was called before the drought.

The leading snow scientist in this country is Dr. J. E. Church, of the University of Nevada, oddly enough a professor of classics, although endowed with the flaming scientific spirit of an Audubon. That Dr. Church should be teaching literature and art, instead of science, is one of Fate's ironies. Enrolled as a youth at the University of Michigan, he took the classical course because he was told it was the hardest. Upon graduation, he was offered a chance to teach Latin at the young University of Nevada He has remained there, honored and contented, ever since. But he was interested chiefly in geology, in the beauty of the mighty Sierras, in exploration, in snow.

In the middle of the winter of 1894, on a dare, he climbed to the summit of Mt. Rose, south of Reno, 10.800 feet high. He attempted a winter ascent of Mt. Whitney, highest peak in California and the United States, only to be foiled when near the summit by a layer of soft snow above a harder crust In 1904 the

All photographs courses The American Geographical Society
At a height of 9000 feet at Contact Pass. A refuge hut and snow survey station
made of sand bags. A wall of rocks on the windward side prevents erosion

problem of the value of forests for conserving snow was being bitterly debated Upon his return from Mt. Whitney, Dr Church, because of his knowledge of conditions in the Sierras, volunteered to procure data. Under the vision of Piesident Joseph E. Stubbs of the University, and the enthusiasm of Samuel B. Doten, later Director of the Nevada Agricultural Experiment Station, which undertook the task, the funds provided by the newly created Federal Adams Act for research were applied to the problem. Mt. Rose Weather Observatory was born, There was little besides hardship in the undertaking, but it added to his snow-knowledge, which most people still thought utterly uscless.

Then there came a winter of deep snows-1906 1907 Lake Tahoc, which hes in the Sierras between Reno and the California plains, rose far above its normal level Cabins along the shore were flooded, and hoat landings were carried away Summer cottagers blamed the power company which had erected a shallow dam above the lake's narrow outlet. When other heavy snows impended they threatened to dynamite it. The power company then called in Professor Church to aid them in guessing how much water would descend into the lake the following spring-and American snow surveying, for practical purposes, was born.

THE depth of mountain snows has been of interest for thousands of years, but it was not until the late inneties that Russian scientists began melting snow to see how much water it contained. Not its depth but its weight determines what water will run off when snow melts. In this country, in 1900, Charles A. Mixer tried melting samples in Maine. He wanted to forecast the run-off of the Androscoggin River and estimate how much of a stream there would be in the spring to float out logs. Only a short time later Robert E. Horton in New York actually drove a tube into

the snow and weighed the snow core.

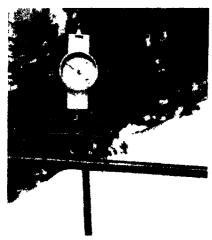

But early estimates based on depth had not been accurate enough. Dr Church devised a measuring tube known as the "Mt Rose snow sampler" It consists of a long pipe, slotted along one side so that you can look into it and poke into it. The depth of snow is measured by a scale on the tube. Then, to determine the all important water content, the core of snow that has been pushed up inside the tube in the measuring process is carefully weighed. The Mt. Rose balance records the net water inches in the snow directly. Thus it is possible to tell how much water there is in a snow field.

Still the job of estimating the total water content of a whole water-hed was too complicated. As a short-cut, Dr Church proposed finding out first what the average snowfall in each region was, by comparing records of different years. After that, all they had to do was find out each spring just how much more, or less, than the average amount of snow had fallen during the month. Half as much snow as usual meant that half as much water would run off next summer. The system of measuring snow only in terms of the average snowfall has now also been universally adopted.

Actually, of course, many other factors enter in. For example, the condition of the mountain soil on which the first snow falls—whether dry and porous or frozen after early rains—makes a great difference in the run-off. A succession of clear, windy days during the period of inn-off may mean some loss of snowwater through evaporation. A heavy thaw in April, or a cold, late spring, may change the order of run-off materially.

One year Dr. Church's early prophecies were nearly 50 percent wrong The expected high water did not occur. To Dr. Church, nature had plainly interfered and he prayed that she would repeat the trick. Lack of precipitation during run-off was soon found to be the cause. But the damage was already done.

An irate irrigation project manager became hostile, and federal funds were withdrawn. Had it not been for Major Paul M. Norboe, of the California State Engineering Department, who had enough vision to foresee how valuable snow-surveying would eventually become, much of the work already done would have gone for nothing. As it was, Major Norboe made an offer from the

A Mt. Rose snow sampler, slotted pipe held horizontally in its balance

State of California to buy all the equipment being abandoned, and continue the experiments. Dr. Church accepted the offer with a thankful enthusiasm such as only a scientist can feel. He got Nevada to combine in a limited way with California in support of the snow-survey continuation, and later on, when the value of the work became more and more apparent, the Experiment Station came into the picture again.

The men who make the actual surveys are foresters, water-men, mountaineers. There are more than a thousand of them They have to be tough. Courses are located at altitudes ranging from 6000 to more than 11,000 feet. Climbing the snow peaks of the Alps, in summer, for fun, is hazardous enough; climbing over the snow-fields of our western mountains, in the dead of winter, to make hundreds of careful, scientific measurements, perhaps with the thermometer far below zero, is more dangerous still.

Although the survey-men regard risks and hardship as all in the day's work, they are never allowed to make their trips alone for, without a companion, a slip might mean even their bones could not be found until spring or summer Mostly they work in pairs or, on longer journeys, in threes. They are ordered to maintain contact with each other at all tunes. Usually they travel on skis or snowshoes over snows that lie 10, 12, sometimes 20 feet deep. In 1917 Mt Rainiei had more than 27 feet, A record depth was reported in 1911 at Blue Lakes, source of the Mokelumma River: 36 feet, 2 inches.

Snow banks 30 to 50 feet deep are not

uncommon, and in the southern Sierras one mountaineer, in summer, saw ax marks on tree-trunks 35 feet above the ground, where a trapper had blazed his winter trail over drifted snow. In Oregon one drift was found to be 110 feet deep

Winter temperatures on the mountains are formidable. When gale-driven they wither the flesh. Near the borders of Wyoming, Idaho, and Utah, 50 degrees below zero is often encountered. Sixtytwo below was noted in Yellowstone Park. In the Ruby and Wasatch Mountains of Nevada and Utah, swings of 70 degrees in a single day are fairly frequent: from 30 above zero, barely freez ing, at noon, to 40 below at night Climbing steep slopes over deep snow. with heavy packs, the men sweat even when the mercury is below zero; then, stopping to rest, they have to be careful not to freeze their hands or feet,

Shelter cabins are built for the surveyors high on the ranges. They are strong, in order to carry the great weight of snow that may pin them down One snow surveyor in Oregon carefully measured the snow on the roof of one small cabin in the Cascades, and found it to weigh almost 13½ tons.

SNOWED-UP cabins are sometimes hard to find. To help locate them, shovels are tied high in nearby trees. Chimneys through which a man can descend are built to save the work of digging down to them. In some cabins, to make sure they can be found, a pole is left sticking up even higher than the chimney.

Before a survey trip is ordered, weather maps are studied as carefully as for a transatlantic flight. When conditions seem favorable the men are ordered out. They go as far as they can by auto, and sometimes a few miles faither on horse-back Then the real climb begins on foot Packs are kept as light as possible. There is a snow sampler, a tube 21 feet long. For ease in carrying, it is made in three-foot sections that can be screwed together. Care has to be taken not to touch the tube with a bare, moist hand when the temperature is very low; the skin would freeze to it instantly.

Surveyors sometimes travel at night to avoid the danger of slides. At Wagon Wheel Gap, Colorado, one surveyor was killed in a slide while his companions were marking snow courses.

The snow courses are from half a mile to three miles long, usually in the form of a letter X. Measurements are taken each year at exact distances, from perhaps 20 to as much as 100 feet apart, at points previously determined, with a total of sometimes 100 samplings for an entire course. Each course provided with a shelter cabin means, as a rule, a three-day trip—one day to get in, one day for snow measurements, and a day to get out. Cabins are stocked with a variety

of dried foods, in tin-lined bins to keep out rats. "Freezing," say the instructions, "has no particularly detrimental effect upon any of the above foods"—the list runs from black tea to canned grape fruit—"during the first year."

So important has snow-surveying now become that an International Commission of Snow was formed in 1933, under the presidency of Dr. Church, with more than 170 prominent scientists representing nearly every country in the northern hemisphere and a few from below the equator. The first meeting was held in Edinburgh in 1936, and Dr. Church was re-elected president. Scientific paperwere offered that, in printed form, total more than 800 pages. The second meeting will be held this year in Washington

Sweden, first European country to adopt the Mount Rose system of snow measurement and surveying, is interested in forecasting stream-flow for running logs to saw-mills. Southern Australia surveys snow to forecast stream flow as a source of power. Switzerland is studying the effect of snow on the formation and movement of avalanche and glaciers. England wants to know more about the effect of snow on the formation of incipient ice-caps. Denmark's

A snow pan protected from falling snow by a special covering or hood

problem is England's in reverse: Danish soil is too sandy and dry, so how can further erosion of soil and snow be checked? Finland is scrutinizing snow-surveys from three different angles: stream-flow for water-power, the relationship between snow and frozen soil, its relationship with frozen harbors. Esthonia, Latvia, Lithuania, and Russia are all interested in the effect of frost and ice on the winter flow of their streams and the choking of intakes. The livers of all those countries are capable of producing power—but they have to be coaxed.

Our own Department of Agriculture estimates that, through snow surveys and the development of all possible water conservation, the 18,000,000 irrigated acres of our western states can eventually be increased to 50,000,000 acres, an area as large as England.

Now Helium Saves Lives

A Mixture of Helium with Oxygen is Beginning to Be Used by Physicians to Tide Respiratory Cripple Cases, Such as Chronic Asthmatics, Over Their Crises

By NORMAN GOLDSMITH, M.D.

An infant lies gasping. Something is blocking his air passages. With each effort to breathe, the spaces on his chest between the little ribs become deeply marked. He keeps growing more and more tired. Soon he will stop trying enticly. If there were only some way to lessen the work those tiny lungs must do.

Since 1934, there has been a way—helium

Most people think of helium as an inert gas, discovered in the Sun's spectrum before it was found on earth, whose sole use is for filling dirigibles because, even though heavier than hydrogen, it is non-inflam mable and the ghosts of the *Hindenburg* still haunt

But there is another use

Basically, air consists of 21 percent oxygen and 79 percent nitrogen Helium weighs only one seventh as much as nitrogen Hence a mixture of 21 percent oxygen and 79 percent helium possesses certain interesting physical qualities. Thus it has only one third the density of an and, more important, requires only about half the effort to pass through a narrow orifice.

Now what has this to do with a respiratory cripple like the infant referred to or a patient with chronic asthma? It means simply that if overtaxed lungs are allowed to breathe a helium-oxygen mixture, they need do only about half the work as if they were breathing ordinary air. To a well person this may not mean much. Put him in such an atmosphere and his voice will sound very high and an ordinary whistle will reach a lofty pitch, but that is all. For a patient with respiratory struggle, however, anything which takes some of the load away may well mean the difference between life and death.

It all started back in 1923, when Charles Cooke received a patent for the use of helium with oxygen for divers,

Courtes Oxygen Equipment Manufacturing Company
Apparatus—cylinder, rebreather, tubes, and tent covering
patient's head—for supplying the oxygen-helium mixture

based on the lesser possibilities of this mixture causing "the bends." Then, in 1926, Sayers and Yant found that animals could be decompressed in a helium atmosphere in one third the time necessary for an

The major contribution, however, toward the treatment of patients was made in 1934 by Dr. Alvan Barach of Columbia University. To prove that the gas was absolutely innocuous he kept mice in a helium oxygen atmosphere for two months. The animals thrived and came out of their artificial environment perfectly well. Following this, he turned his attention to humans. Patients have been in such an atmosphere as long as four and a half days and, to prove that there were no harmful effects, he has had professional singers switch from one medium to the other without ill effect.

In what conditions is the heliumoxygen mixture of use? Asthma, certain anesthesia difficulties, any obstruction of the air passages, and asphyxia of the newborn If we take the infant who was struggling so pitifully, with his rib spaces deeply accented, and place him in the helium atmosphere, his chest wall smooths out and he breathes comfortably. Or take the old man wheezing with chronic asthma, his lung tissues so fatigued that they react no longer to adrenalin. Place him in the new atmosphere and he has time literally to catch his breath. His apprehension diminishes

and he may be able to sleep. Such treatment may be continuous for from one to five days or intermittent—a few hours each day. In grave cases, such measures have proved life-saving. Also, the tissues again become able to react to adrenalin and the patient acquires a new lease on life

Now helium-oxygen is not a cure. It is merely an aid in the same sense that an elevator is an aid to a person with a bad heart or a cane to one with a defective leg. The mixture saves work and, when the patient comes out, the temporary rest may give him enough strength to carry on himself. Further attacks for a while may be less frequent.

How much does helium cost? All helium is owned

by the United States government but special dispensations have been made for its use by practising physicians, an interesting contrast to the government's refusal to sell the gas to Germany for a possible war use. The gas is sold in cylinders which contain about 200 cubic feet, an ample quantity for one patient for 24 hours. The charge for this is between \$10 and \$14, depending on freight distances.

Distribution is through the same channels as oxygen, there being approximately 50 oxygen supply companies in the New York area alone. The giving of helium is more difficult than that of oxygen since it is necessary to maintain the actual concentrations of the two gases without any inward leakage by nitrogen This is obtained by a special hood tent which fits around the neck. Special accessories permit considerable salvage for rebreathing, as shown in the illustration on this page.

Already the helium-oxygen mixture has been employed, in addition to New York, in Washington, San Francisco, Boston, Cincinnati, and at the Mayo Clinic

Biskupin

By J. KOSTREWSKI

THE village of Biskupin is situated in the northern part of Great Poland, 65 miles to the northeast of Poznań and to the southwest of Toruń, the capital of Polish Pomerania. Nowadays it is famous, not only in Poland but throughout the world, for the remarkable discoveries made in its vicinity by the Poznań University Archeological Expedition, Excavations have been carried on for four years, and have revealed the ground plan of a prehistoric stronghold which was built on a peninsula jutting into the lake of Biskupin, on the surface of a former peat bog, in the Early Iron Age, between 700 and 400 B . . but abandoned in consequence of its inundation by the waters of the lake. The site was covered with a thick deposit of sand and mud, which protected the remains against atmospheric influences, while the dampness of the ground caused the preservation in excellent condition of the lower portions of the huts and the wooden defensive works, as well as the roads and breakwaters.

During the Bronze and the Early Iron Ages a great part of western and central Poland as well as eastern Germany was inhabited by an agricultural people known as the Urnfield people, of Lusatian type, and who are considered by nearly all Polish prehistorians as ancient Slavonic. Being threatened with invasion by the cist-grave and face-urn people of Pomerania, who were probably of ancient Baltic stock, they took refuge in forts constructed of wood and earth placed in inaccessible spots, for the most part on islands and peninsulas. Nothing but the necessity of defense can have induced the prehistoric inhabitants of the neighborhood of the present Biskupin to establish themselves on the damp and peaty peninsula extending into the lake, which was both unhealthy and unsuitable for building. This peninsula, surrounded on three sides by the lake and cut off on the land side by a broad strip of marshy ground, was further fortified, as the excavations hitherto made have indicated, by a wooden rampart filled with beaten earth, which was carried round the whole site. This rampart was built three times, and each time nearer to the center of the peninsula. Only small fragments of the earliest and northernmost have survived; it was clearly destroyed by water. Later the area enclosed within ramparts was re-From Antiquity

duced and the first breakwater constructed, and within its shelter a second rampart was raised. When this latter was partially destroyed by fire, it was replaced throughout a considerable length by a third, rather narrower, wooden rampart eight feet wide, running parallel inside and south of it, which however is not continuous, but is interrupted by a row of huts, because the old rampart was well preserved at this point. It was constructed of beams, overlapping and placed crosswise, chamfered at the intersections for security, and supported by piles driven in vertically on the inner side. The result was two or three rows of caisson-like chests, which were then filled with stamped earth. Considerable remains of the middle and latest rampart, in places as much as three feet high, have been laid bare in the north and east of the peninsula, while on the south the rest of the rampart, which once prevented access on the land side, can even now be clearly identified.

ALONG the middle rampart a row of piles were driven in obliquely to protect it against the undermining action of the waves. Farther toward the lake is a double row of similar piles, constituting the oldest actual breakwater, and beyond it again another, consisting of seven or eight rows of great piles driven obliquely into the edge of the lake and strengthened by the imposition of

horizontal beams. The innermost of these breakwaters is considerably lower-perhaps two and a half feet-than the second. Obviously, then, the original low breakwater had to be replaced by a new one. higher and a little farther toward the lake, owing to the rise in the water level. Access to the rampart was facilitated by a circular street running along the inner side of it, and three great piles, driven into the edge of this road at a point where a sharp turn rendered it difficult to build a house, seem to have supported a kind of gangway leading on to the top. Within the latest rampart were found heaps of stones, apparently laid there to be hurled against an advancing

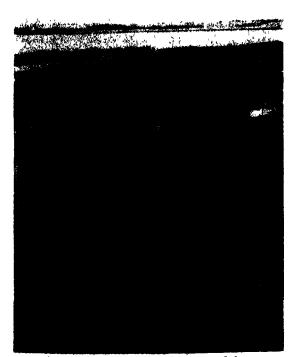

The area thus fortified was occupied by a populous settlement, composed of from 80 to 100 huts, built on a layer of birch fascines resting on the surface of the peat-bog. The ground plan was laid out in a masterly fashion which would have done no discredit to a modern town planner. In the area so far excavated eight perfectly parallel roads or lanes have been laid bare, running from west to east and connected by an outer one, running round in a half circle within the rampart. These lanes were of corduroy construction, that is to say, made of thick oak logs. On either side of each street were rows of wooden huts standing end to end and actually touching. Indeed there was frequently only a single common end wall. The huts were about ten yards square, and their doors, sometimes eight feet across, were always on the south side, evidently serving to let in light. These huts usually contained two rooms; a main one with the hearth and a vestibule, six or eight feet broad, which took up the whole front. Sometimes, the main space was divided into two compartments; one, smaller than the other, having perhaps served for the accommo-

Remains of wooden ramparts at Biskupin, surrounded by the expedition's dyke. Remnants of the earliest ramparts show at right—successive once to the left

dation of cattle or as a sleeping-room. To the right of the entrance, in the main room, was the round (rarely square) hearth, most frequently made of stones and as much as six feet in diameter, but occasionally of nothing but clay. The floors were composed of wooden beams resting on fascines of crossed or sometimes interwoven birch sticks and branches, and were covered with a layer of clay to diminish the danger of fire. The stone hearths themselves were also overlaid with clay, which preserved them from being blackened or split by the heat.

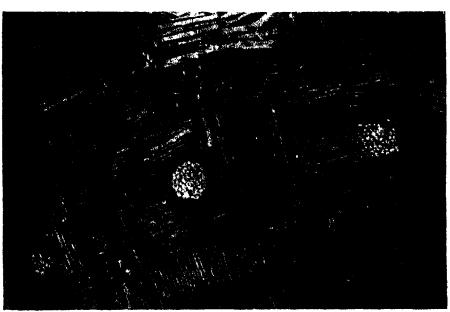

All the houses are built on the same plan. At the corners are placed round posts of pine, in each of which are cut two vertical grooves, running the whole length of the post, an angle of 90 degrees separating the one from the other. Between these corner posts are flat ones, usually of oak, with two vertical grooves. Into these grooves are fitted, one upon another, beams or rough-hewn planks with flattened ends. In some of the better preserved huts as many as three still remain in position. The door posts were also grooved on the outsides, their door sides being smooth. At the bottom all these posts were supported by cross pieces running through them and pro-

At left center, entrance to a hut; at left top, some of the ramparts and, at the extreme left, part of the circum-peninsular road or street

jecting on either side, to prevent them sinking in the peat-bog. This method of building is still employed in various parts of Poland, and even at Biskupin itself there is a peasant's cottage constructed on exactly the same principle, so it may be that an ancient building tradition has been preserved for 2500 years. As the upper parts of the huts have been destroyed, it would have

The Excavation of an Early Iron Age Village in Eastern Europe Brings to Light Artifacts Showing the Daily Life of a People of about 2500 Years Ago

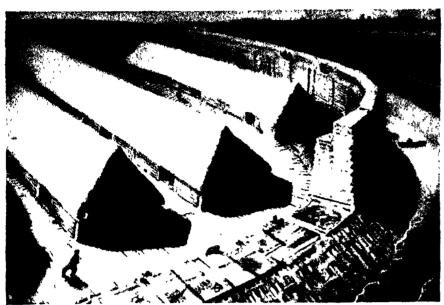

Vertical view of two huts comprising three rooms; also the middle rampart

been impossible to estimate the height had not two or three posts from destroyed ones been preserved by being used a second time in the floors or the lower parts of the walls. Some of these are 13 feet long, so that, allowing for three feet in the bog, the height of the walls was probably ten feet.

A number of observations go to show that the huts excavated at Biskupin are not all of one date. Huts were frequently destroyed by fire, and new ones built on the same site, in which case remains of the old ones were so far as possible incorporated in the new. In some, therefore, we find two door posts side by side, or two corner posts, or flat wall beams from two separate huts that were built in succession on the same site; indeed there are occasionally remains of three huts built one after the

other on the same site at different periods. Two floors and two hearths, one above the other, are found comparatively frequently, separated by a layer of soil 12 to 20 inches thick, and there are a few examples, especially in the lower or northerly portion of the area, of two or three levels in a street. In either case the lower level, alike in hut and street, is solidly constructed of thick

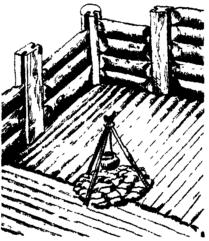

oak trunks while the upper is carelessly and hastily composed of thin birch poles. These later road and floor surfaces are evidently to be connected with some great flood which inundated the settlement and compelled the inhabitants to raise its level. When this settlement was founded the level of the lake must have been considerably lower than it is today, even though it was markedly lowered a few years ago by the deepening of the Gasawka stream, which runs through it. Evidence of this is found in the fact that the hearths of many huts which have been excavated are now below the surface of the lake. During the course of the settlement's existence, however, there must have been a marked increase in the volume of water in the lake, due not only to local causes such as the silting of the bed of the Gasawka, but also to a general increase of rainfall; for the researches of paleobotanists show that in the Early Iron Age the climate of Poland, in common with that of a considerable part of Europe, was steadily becoming damper and colder. Our excavations confirm this for the northern part of Poland. The influx of water due to the increased rainfall seems finally to have become so great that the inhabitants abandoned the flooded site. But that which was a catastrophe for them has turned out a blessing for archeology. For, although everything which was above water level has been completely destroyed, the foundations and lower parts of the huts and the other constructions, covered with

A reconstruction of the northern part of the village, as drawn by W. Boratvuski

water and earth, have been preserved almost as they were left 2300 years ago

This protective layer of sand and mud has also preserved a large number of tools, ornaments, and weapons used by the ancient inhabitants, and even a few pieces of furniture such as the lower part of a family plank bed discovered in one of the huts. Pottery especially is very well represented Besides coarse ware there are some very beautiful, richly ornamented specimens: for example, incised vessels encrusted with white material or painted with red other, lumps of which have been found on the site. Two vessels are decorated with very conventional figure-drawings: a few riders, and a hunting scene with several horsemen and two stags. There are numerous bronze objects, 40 pms, some of them swan necked, a few bracelets and small rings, needles, fishhooks, a razor, tweezers, double cone-shaped beads, buttons, and many other objects. Iron socketed celts, sickles, awls tone of them still in its bone handle), needles, a bridle bit and pins have been found; as well as horn and hone awls, mattocks, large hammers with square holes for the handles, socketed spearheads, tanged arrow heads with barbs, smoothing tools, and so on Wooden implements include swirling sticks, pestles, two kneading troughs, pine bark floats for fishing nets The most interesting wooden objects are a primitive plough, a solid wagon wheel of Mercurago type, made of a single block of wood, with a square hole for the axle and two semicircular openings cut out on either side, strengthened by two strips let into the wood across the grain, an oak axle from a cart, and three wooden gratings, one of them lined with wicker, which were doubtless used as hut doors. Other finds include blue glass beads, most probably imported from Egypt, various stone implements such as pentagonal celts, circular and triangu-

Showing the original method of construction of the huts at Biskupin

lar tools the purpose of which is unknown, but which may have been used to smooth carthenware vessels or to prepare hides, querns and grindstones, clay implements for spinning and weaving, whorls and loom weights, and clay toys. The numerous carbonized grains of corn, wheat, harley, millet, pea, and vetch which have been found, and fibers of flax, point to the agricultural character of the population. The bones of domestic animals found show the importance attached to cattle breeding. Wild creatures are represented mostly by the stag and the hare, more rarely by the bear, and occasionally by the wild boar, the wolf, the fox, the heaver, the wild duck, and the hawk. Fish bones occur but rarely. Other occupations of the people are clearly illustrated by the discovery of clay molds for casting necklaces, pins, and the like. They are all of the socalled cire-perdue type, that is to say the clay was plastered around the wax model, and, after casting, the mold had to be broken in order to get at the object. Such models, for this process, have not hitherto been found elsewhere in Poland.

The excavations at Biskupin have given us for the first time a conception of the appearance of a complete prehistoric Polish settlement, and have thrown new light on the material and social culture of the Urnfield people of the Lusatian culture. Only a well-disciplined body of men under energetic leadership could establish such a settlement and build it according to a unified and wellthought-out plan. It has sometimes been supposed that the Lusatian culture disappeared as the result of over-refinement and consequent decadence; but the discoveries at Biskupin give us a very different picture. The frequent occurrence of horn and bone implements on a site dating from a period of the highest development of the Lusatian culture, when bronze was beginning to be superseded by iron, offers a perfect analogy with the frequent use of horn and bone implements by the early historic Slavs-between A.D. 600 and 1000-who also raised similar strongholds and showed a similar tendency to settle on low-lying ground exposed to inundation. The most striking fact is that huts of identical construction are in use today over the whole area once occupied by the Lusatian culture, especially in Poland There are some, indeed, quite close to our site, at Godawy, on the east bank of the lake of Biskupin and at Biskupin itself. A similar hut, dating from the late Middle Ages, was excavated in 1935 at Keynia in the district of Szubin, and another dating from the 17th or 18th Century, at Ostrowo near Gebice in the district of Mogilno, and it may be therefore supposed that the type has existed in Poland continuously from the Early Iron Age down to the present day, if this is true it supplies one more proof of the Slavonic origin of Lusatian culture.

THE complete examination.

Kupin will take several years, for which the site covers over six acres, of which only one third has so far been excavated. The best preserved portion, it is hoped, will be properly protected and kept as an object lesson for future gencrations. The archeological expedition hves on the spot in a camp of its own, containing a workshop, a dark room for photography, rooms for drawing, and so on. The whole site laid bare is mapped on a scale of 1:10 and several hundred photographs have been taken from ladders and from a balloon. The expedition has reconstructed two huts on the original plan, one of which serves as a museum, where the most interesting finds are exhibited.

Coming soon: The inside story of television as it will be presented to the American public in scheduled broadcasts to start this spring.—The Editor.

unbelievably simple.

Ingenious Factory Process Solves Old Problem . . . Lower Cost . . . Transformer is Significant

() basic change has occurred in the design of the transformer, inert device for increasing or decreasing voltage of alternating current circuits, for more than 50 years Back in 1886, at Great Barrington, Massachusetts, Wilham Stanley developed and put into first practical use a transformer which, except for certain refinements, is the same in construction and principle as those in use

Now, however, a transformer developed by the General Electric Company, embodying an entirely new construction principle, has been placed on the market Although the operating advantages of the new type transformer, as well as its lower production cost, are economically significant, the manner in which the device is made is the more intriguing

The transformer is known as a "woundcore" type and embodies the solution to a design problem that has stumped the

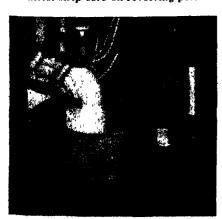

cially developed machine which accomplishes the feat efficiently in a matter of a few minutes, as compared with the appreciably longer time required to hand-assemble the L-shaped steel punch-

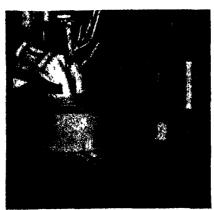

End of strip threaded through coil window and loosely around post

Process begins with pre-wound metal strip core on revolving post

All of strip is unwound from post and is loose loop through window

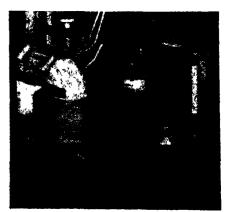

Post retracted, the inner end of core strip is pulled in around coil

ings regarded as most efficient for the core construction of old-type transformers.

This accomplishment of winding the cores about the coils seems like a process that should present no great difficulty, and it wouldn't-except for the fact that the pre-wound shape of the core must be retained throughout the process. The outer turn of the core in its pre-wound form must be the outer turn of the core after it has been wound on the coils; and the inner turn must likewise remain the inner turn after the winding process is completed. This precaution is necessary because the spiral cores have been "set" in their pre-wound shape by carefully controlled annealing operations to retain the superior magnetic qualities in the steel If the form of the core is too greatly disturbed in the winding process, small elastic stresses are caused and may increase the electric losses in the core steel by as much as 15 percent. Reversing the order of the turns might increase these losses as much as 25 percent!

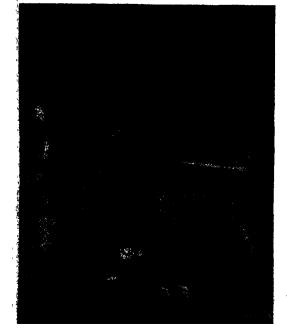

In the winding process, the pre-wound core is placed on a post adjacent to the coil assembly on the special machine Then the outer turn of the spiral core is passed through the "window" formed by the coil winding, brought around in a fairly large loop, and tack-welded to the next underlying strip of the roll By means of a series of revolving rollers, both the core and the large loop which has been formed by its outside turn are rotated. In this way the strip is unwound from the post and simultaneously rewound about the coil in its original form. The same operation is repeated on the other leg of the winding, and presto!the transformer assembly has assumed its misleading semblance of the linked rings of the magician

Outside rollers now roll the strip into a tight spiral around the coll

1 Foreign substances are removed from the crude rubber that will eventually become part of one of your automobile tires. In this machine the crude rubber passes through close-set rollers which chew the rubber and expose many surfaces for cleaning by a spray of water

4. Cotton now enters the picture. From it is made the cord which, in the illustration below, is being covered with rubber, each individual strand receiving its coating. Thus cord and rubber are merged to form the tire fabric. This type of construction is considered to be an important safeguard against tire deterioration through heat generated when the tire is in use

Rubber to Cotton

Rubber Thoroughly Cleaned . . . Ingredients Mixed . . . Cotton Cords Individually Coated With Rubber . . . Wire Beads . . . Treads Extruded in Slabs

By A. P. PECK

2 Below: The cleaned naw rubber is next worked into a plastic condition, after which it is combined with other materials, necessary to tire wearing qualities, in a machine such as that shown

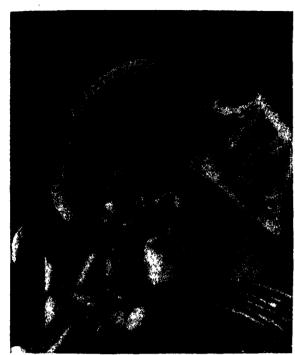

Among the basic machines in the tire manufacturing industry is the rubber mill shown above. Here the mixture made in the machine shown at the left is passed between rollers so that the raw rubber and the added ingredients are compounded thoroughly. If this is not carefully done, mixing will be incomplete and the finished tires will not be wholly satisfactory

5 Sheets of tire fabric, formed of rubber impregnated cords, are cut to specified widths and angles as shown below. Practically all fabric now used in tire construction is cut on the bias on machines such as this to afford strength and flexibility, and hence greater satisfaction and higher road safety for the ultimate consumer—the motorist

TO TIRES

6 The head or edge of the tire is formed of woven copper wire, incased in a sheath of rubber and fabric. There are approximately 137 feet of this wire in the head used in an average size modern passenger car tire

8 Right A skilled workman in one of the plants of the B. F. Goodrich Company is assembling the various parts of a tire built by the "drum" process. The layers of cord are rolled smooth and the beads with their re-inforcing strips are tied into the carcass. After breaker strips, cushion, and tread are applied, the drum is collapsed and the uncured tire is removed

Right: Preparing the strip of rubber which eventually will become the tread of a finished tire, bearing the distinguishing design of its manufacturer. Here the rubber batch is placed in the machine and extruded as a slab of rubber of the desired width. The tread is then ready for application to the completed tire body

9 Below: The forming chamber where the tires built by the drum method are shaped. The casing, as it comes from the assembling drum (see 8, above), is placed in this chamber and a water bag inserted by means of a ram. Pressure built up in this bag forces the tire into the circular shape in which it will be vulcanized

10 Below: The shaped but uncured tires are here placed in steel molds where the tread design will be impressed. Still in these molds, the tire is vulcanized by steam and hot water

Below: Finished tires pass before a group of inspectors whose sharp eyes detect any minor imperfections that might injure the serviceability of the tire

A MONTHLY DIGEST

Invisible Glass

CLARE from reflected light, which makes it difficult to see pictures framed under glass at certain angles, has been removed by a new process developed in General Electric's research laboratory by Dr. Katharine B Blodgett By applying thin chemical films to the surface of

Dr. Blodgett demonstrating how the anti-glare surface is put on glass

glass, Dr. Blodgett has been able to nullify or neutralize reflected light rays with the result that pictures framed with glass so treated appear as though there was no glass at all, regardless of the angle of view. The same is true with clock faces, show cases, display windows, in fact, any place where glare is caused by light reflections on glass.

The refractive index of any type glass is easily determined. This known, the process consists of huilding or attaching to the glass a very thin transparent film of about four milliontus of an inch, or exactly one quarter wavelength of light, in thickness. As light falls upon the film, rays are reflected from both the upper and lower surfaces. With the film exactly one quarter wavelength in thickness, those rays coming from the outer or upper surface are equal in intensity and opposite in phase to those rays reflected from the lower surface, and counteract one another; thus no light is reflected.

"The process is still in a laboratory

Conducted by F. D. McHUGH

ALEXANDER KLEMIN

In charge, Daniel Guggenheim School of Aeronautics, New York University

D. H. KILLEFFER Chemical Engineer

stage," Dr Blodgett explained "At present it has not reached such a stage that it can be offered the public However, we are hopeful that we may soon do so.

"Glass is treated by dipping it into a tank of liquid, on the surface of which is a film of insoluble soap but one molecule thick. As the glass is pushed down one layer of the film becomes attached and as it is pulled up another is applied. Thus

The clear part of this framed portrait is covered with the new invisible glass, the rest with ordinary glass to show the difference

cach immersion adds two layers of the film, each but one molecule thick. The dippings are continued until we have built up about 44 layers which form a thickness of one quarter wavelength, or about four millionths of an inch. We can measure or determine the exact thickness of the film at any time, although it may be thinner

than any substance we know of today, by an optical process

"The non-glare treatment of glass also promises to have a wide-spread application in the field of camera, telescope, and all other type lenses," Dr. Blodgett pointed "It is commonly known that reflection from the surface of any lens causes from 4 to 5 percent loss in the light transmitted Since this is true to both front and back surfaces, there is a light loss of at least 8 percent in each lens With some of the better type cameras, using three or four lenses, the loss of light reaching the plate or negative is 25 to 35 percent. With telescopes and submarine periscopes, where a larger number of lenses and prisms are used, the light loss is still greater. In some periscopes it is as much as 75 percent.

"With the exception of the slight loss by absorption in the glass itself, the film-treated lenses would transmit 100 percent of the light. With an actual test in the laboratory, a piece of glass was treated and by doing so we increased the light transmission from 92 percent to 992 percent."

WELDED METAL SCULPTURE

A WELDER, and a good one, is F. F. Nichols of David City, Nebraska. During the summer he has little time for hobbies but in the winter months he takes a hand in some unusual creative work of his own.

No soap sculpture or basement workshop

Figures created by welding

carpentry for him. Turning away from repairing castings of massive proportions, Mr. Nichols takes up his oxy-acetylene welding blowpipe, some steel welding rods and some bronze ones, a few additional light sheets of steel, and sets to work fashioning small metal figures depicting life and action in the old West. These figurines have a vitality and vigor that might be found in the work of a craftsman of the Renaissance. Yet the hands and equipment that shape them are the same that each year repair and fabricate tons of heavy industrial equipment.

The solid body portions are built up with a melted steel rod and then given a lustrous coating of bronze with the bronze welding red Exact blowpipe control of the direction of the intensely hot flame and skilful manupulation of the welding rod make possible the careful shaping of each figure. The patina, or surface color of the bronze coating, is obtained by varying the flame to get different effects of shading

AFTER DEATH

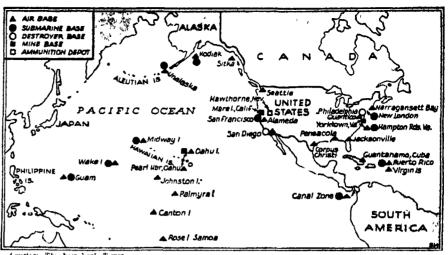

ELECTROCARDIOGRAMS have shown that the heart beats for as long as half an hour after a person is, to all appearances, dead. The stethoscope is not reliable as a means of determining whether the heart's action has ceased. Artificial respiration should be continued until rigor mortis sets in-Health News, New York State Department of Health.

LIGHT-WEIGHT FREIGHT CARS

ANTICIPATING the need for light-weight freight equipment, American Car and Loundry Company has developed two new designs of modern light-weight welded steel freight cars. One is a 50-ton all-welded alloy steel box car and the other a 40 ton weldedriveted refrigerator car.

Low alloy, high-tensile, corrosion-resisting steel has been used to the fullest extent practicable in both types of cars, the thickness of plates and shapes being reduced to a minimum while still providing adequate strength. The light-weight of the box car is 37,500 pounds and that of the refrigerator car 44,200 pounds. This represents a reduction in weight of approximately four tons in each design.

New developments incorporated in the allwelded box car include steel ends with extra long corrugations extending around the body

Careful study has been made by a Naval Board of the coastlines of the United States and its possessions. This Board recently made its report to Congress. The above man shows the Board's recommendations as to sites and types of bases which are deemed necessary. Because of the desire to unify our defense plans, most of these bases will be approved and construction work will be started without delay. At least the nation can count on a vast extension of our system of air bases

end posts, steel doors of increased rigidity, and a new design of under-frame having integral all-welded construction

New developments in the welded-riveted refrigerator car, in addition to those mentioned above, include ice bunker, ice hatch, removable steel bulkhead, a unique and very efficient application of insulation, and a new and economical method of using dry ice in combination with water ice

SLAG IN GLASS

N India, where soda ash is relatively expensive, experiments have been made to show that the slags of iron and steel plants can be used in the manufacture of glass for many common articles. The slag used is supplemented by orthoclase feldspar. Reduction in the cost of common glass, as made in India, of as much as 50 percent is reported. The glass has been used for bottles, jars, tiles, and such articles -D H K.

PERU'S GOOD-WILL OFFER

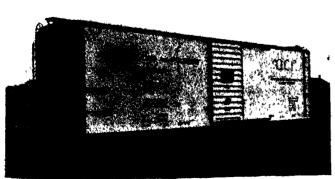

DURING the recent session of the Pan American Conference at Lima, Peru, the New Orleans office of the Pan American Society of Tropical Research received an official communication from the Honorable Pedro Recavarren C, Director of Agriculture of the Peruvian Government to the effect that the people and the government of Peru desired to make a good-will gift offering, to the citizens of North America, substantially as follows.

"In celebration and commemoration of the successful International American Conference (Pan American Conference), at Lima, Peru, South America, the people and government of Peru take great pleasure in offering, through the good offices of the Pan American Society of Tropical Research of New Orleans, Louisiana, United States of America, a free, good-will packet of seeds of a beautiful native flowering plant of Peru. This offering is an expression of the feeling of peace and kindness that exists in South America for the people of North America.

The seeds offered are those of the Mutuy Pacte, which is a small plant, bearing flowers of exquisite fragrance and exotic loveliness, that is native to the mountains and highlands of Peru. It is, therefore, hardy and can be grown throughout the latitudes of North America. The color of the flower is a brilliant shade of yellow and the plant blooms for two or three years.

In connection with the free seed offering of this beautiful Peruvian flowering plant, a pamphlet will also be sent to applicants that will describe the results attained by the Pan American Powers at the recent International Conference at Lima, Peru, and also will describe the country of Peru and carry the message of good-will from the Peruvian people and government to the people of North America."

This pamphlet and a packet of these seeds

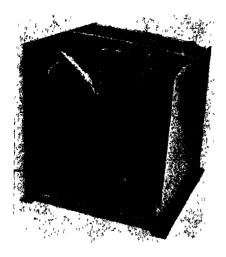

Two new types of freight care constructed of light-weight alloys

will be sent to every person in the United States and the Dominion of Canada who desires them. There is, of course, no charge and no obligation. Send your name, address and a loose stamp to: The Pan American Society of Tropical Research at New Orleans, Louisiana. Eight hundred thousand seeds of this Peruvian flowering native plant are ready for distribution. Peru invites you to write for your free packet of seeds and measage of good-will now.

FUEL TANKS OF FABRIC

THE Glenn L. Martin Company has now developed an aircraft gasoline tank of synthetic fabric which gives definite promise of being vibration-proof and thus insuring higher safety and reliability.

In the "Mareng fuel cell," as it is called, the gas-tight metal fuel tank is eliminated Bags of treated fabric are designed to the shape of the interior compartments of wings, fusclage, or floats, as the case may be, and are inserted in place somewhat as inner tubes are installed in tire casings. These fabric tanks, instead of being tailored to fit their compartments exactly, are cut to patterns which are slightly larger in each dimension than the surrounding walls against which they rest. This over-sizing is an

Above: One of the new fabric fuel tanks for aircraft, showing how it is placed within a metal compartment that serves as a container

Right. Fabric fuel tanks installed in a wing, before the bottom plate is fastened in position

Lower right. The "shaketable" set-up on which airplane fuel tanks are tested to determine the resistance to vibration

important factor, as the fabric liming is thus never subject to stretching or twisting. The cell serves solely as a static, vibration-proof container, all strains and stresses being taken by the structure of the wing fuselage or float

Government specifications require that airplane gasoline tanks shall be able to withstand not less than 15 hours of destructive

vibration on a high-frequency vibrating table, and 25 hours' resistance is the highest requirement in any service. Subjected to this vibration the Mareng fuel cell withstood 700 hours of test unscathed, although to make the ordeal more severe a rocking motion was also imparted to the machine. One of our photographs shows the table to which a high-frequency, low amplitude vibration imparted while the tank is undergoing test. The arm at the right supplies the rocking motion.

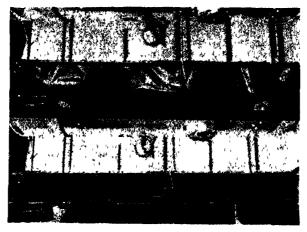

In another photograph is shown one of the fabric cells placed loosely within the metal compartment, which is subsequently placed on the vibrating table. A third picture shows a three-cell fuel tank installed in a plane wing.

Another advantage of the new type of tank 14 that, if pierced by a bullet in flight, the leakage of gasoline is relatively slow Piercing treated fabric results in a slit, rather than in a definite hole. Under the pressure of the gasoline the slit tends to close. On a foreign war front, one of the new Martin fabric tanks was pierced by enemy bullets Instead of the plane being immediately grounded, as would be the case with conventional metal tanks, it was able to return to its base more than a hundred miles away Still another advantage, besides the climination of gas tightness in the structure, is the fact that corrosion of metal by gasoline is no longer to be feared. Gasoline inside the cells is not in contact with metal, and the synthetic fabric is completely unaffected by gasoline.

While the new development is perhaps of more interest in military applications, it should add greater reliability to commercial aircraft likewise — 4. K

SEAPLANE TERMINALS

THE Scaplane Flying Association wants the C.A.A. to create a Division of Scaplane Operation to build seaplane terminals and pertinent facilities. If we accept the Division of Private Flying, then a Division of Seaplane Flying is equally logical. The question of costs, and the effect of costs on the

national budget, is something which should always be kept in mind, however, when a new federal activity is suggested.

Even today the C.A.A. is not neglecting the seaplane. Thus, its airport section is developing a new floating marker light, for night operation of seaplanes and flying hoats. These lights have already been tried out in the vicinity of Baltimore, Maryland,

where a 3600-foot landing area was laid out by mooring two rows of twelve lights each, spaced 300 feet apart on the surface of the water. A series of experimental take-offs and landings were successfully carried out within this area with a Douglas Amphibian and two Navy Consolidated Flying boats.

The construction of the light is very simple and effective. It consists of a 39-inch streamlined airplane tire floating on the water, through which a five-foot vertical bronze tube is set in gimbals. A 25-pound battery container is fixed at the bottom of the tube and a mercury-vapor light at the top. An anchor weighing five pounds is made fast to the float with 36 feet of chain, so that it remains relatively stationary in rough water.

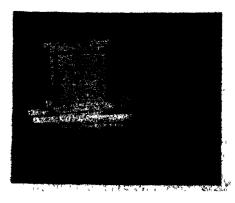

It is believed that the new system of water lighting will reduce surface glare, give the pilot a definite horizon, and indicate the exact surface of the water. It will be interesting to see how the system works out in continued service—A K.

Our Position in Air Defense

FOREIGN governments are secretive in matters relating to military and naval aircraft-far more secretive than is our own government--and no comparison of foreign air fleets and of our own air fleet is entirely sound But this is what may be deduced from reports of competent American observers of the European scene, such as Igor Sikorsky, Paul Johnson, and others. In prototype airplanes-that is to say, airplanes which are types and not yet in large production-we can match anything that England, Germany, France, or Italy has to show us. If some single-seater fighters in England and Germany are faster than ours, this is only because our single-seater fighters confront longer distances in service and have to carry much greater fuel supplies. Otherwise, in hombers, multiplace fighters, navy patrol boats, or what not, we are either unsurpassed or definitely ahead. But when it comes to actual airpower, and current production of military aircraft, then it may be said that we lag behind, particularly behind

Mr. Johnson, with considerable evidence to back up his statement, rates the actual air powers of the great nations as follows: Germany, 10; Italy, 6; Great Britain, 5; the United States, 4; and France, 2. C. G. Grey, in Jane's "All the World's Aircraft," dismisses Russian aviation as negligible, and social experimentation on a vast scale seems to have reduced French strength and current production of aircraft to a very low level.

It is quite apparent, then, that the Administration is fully justified in seeking a great

increase in our air forces and the building of 9000 to 12,000 airplanes in the next two or three years. While the program is ambinous, the productive genius of the United States will undoubtedly be equal to the task. Where we may find greater difficulty is in training flight personnel, and in getting enough mechanics for maintenance and other ground duties. Without adequate ground forces, the mightiest air fleet is help-less.—A. K.

PROPELLER PROGRESS

THE year 1938 was remarkable for many aviation achievements such as the "hydromatic" controllable pitch propeller which keeps the engine running at one particular speed, and at the same time allows the constant speed to be set at any desired revolutions per minute; the electrically controllable propeller; the fully feathering propeller in which the blades can be set edgewise when an engine is out of commission, and the development of a system in which an engine drives one airscrew to the right and another to the left so that engine torque effects are eliminated. In addition to all these advances, the propeller engineers are keeping a jump ahead of the game by building airscrews large enough, yet not too heavy, to absorb the power of the 2000 horsepower engines which are just around the corner.

One of our photographs shows a Hamilton

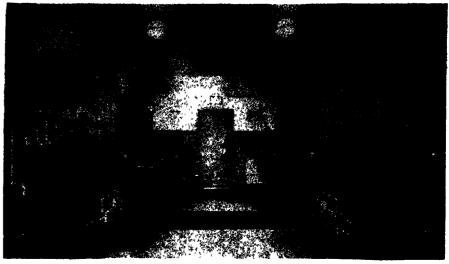

Latest in propeller design

Standard 17-foot hydromatic propeller, the largest propeller ever built, designed for use with airplanes which are still in the drafting-room stage. This 17-foot giant dwarfs the 11½-foot airscrew now in use on the Douglas DC-3 transport. The largest metal propeller actually in use is the 14-foot airscrew employed on the new Boeing 314 flying loat.—A. K.

CIVIL AERONAUTICS AUTHORITY

AFTER some preliminary confusion, unavoidable, in organization, the Civil Aeronautics Authority has got into its stride and is doing good work. Perhaps the most significant innovation of the Authority is the creation of a Division of Private Flying, with Grove Webster as its chief. Mr. Webster will attempt the simplification of air regulations affelding the private flier; develor wasterstined methods of ground school

One of the sound-proofed control rooms from which engineers observe airplane motors on test. Left: The flexible cable mounting or supports of powerful engines in their test cells

and flight instruction; maintain contact with private fliers throughout the country; and in general promote popular flying One of the most important tasks facing

the new chief is to help in the provision of inexpensive flight instruction. College students as a class are excellent flying material, and are just at the right age-old enough to have discretion, young enough to pick up flying quite readily. But they are not at the earning stage, and parents refuse to provide the 200 or 300 dollars necessary to learn to fly. If Mr. Webster can help the formation of clubs, arrange for payments to those who have solved or otherwise reduce the financial liabilities of a college boy learning to fly, he will undoubtedly increase the number of amateur pilots by thousands. It will be interesting to see what policy is finally evolved .- 4. K.

TESTING AIRCRAFT ENGINES OF 3000 HORSEPOWER

AIRCRAFT engines are constantly increasing in power, and the Wright Aeronautical Corporation is putting into production double-row Cyclone engines rated at 1500 horsepower, the highest ever accorded an aircraft engine of any type by the Civil Aeronautics Authority. And, of course, the engineers and constructors will not stop at even this immense power.

These powerful prime movers are based

on the most exhaustive research, and among other problems there is that of testing, particularly of testing many powerful engines simultaneously for long periods of operation. To meet the situation, a building has been constructed, enclosing a battery of 14 test cells, each of which is capable of testing an engine up to 3000 horsepower, swinging huge propellers up to 20 feet in diameter.

One of the most interesting features of the new equipment is the investigation of air effects on the engine under high-speed flight conditions. When air enters the carburetor at 200 miles an hour, there is a powerful "ramming" effect. A blower connected to the carburetor air intake enables the test engineers to simulate this "ramming." The blower is also equipped with controls by means of which the air fed to the carburetor may be "thinned" out to simulate flight at high altitudes. The air may also be heated or cooled to represent varying atmospheric conditions.

The test cells are built in pairs and are separated by control rooms on each side of which are tables on which are mounted the throttles and a variety of instruments for checking power output, fuel and oil consumption, cooling, and so on. A glass window above the instrument board gives the test engineer an unobstructed view of the test cell and the engine.

Soundproofing is another problem. The inhabitants of Paterson, New Jersey, used to complain bitterly of the unendurable noise created by engines undergoing test. The walls of the building are now so massive that no noise can penetrate them, but the inlet and exhaust air must be rendered incapable of spreading sound waves into the surrounding atmosphere. Hence the towers at each end of the test cell, which extend 30 feet above the ground, are provided with a great concentration of sound-absorbing material. The offices of the test engineers are also most carefully sound insulated.

A new method of mounting the engines has also been developed which simulates actual flight conditions much better than the ordinary framework of structural steel bolted to the floor. A steel tube is used instead. This tube is suspended from the ceiling

by four cables and anchored to the floor by two more. Cradled in rubber, these cables provide a flexibility in the engine mount which could not be obtained with a rigid test stand. They also prevent the transmission of vibrations to the walls of the structure.—A. K.

X-RAY TIRE INSPECTION

WITH the attention of every safety organization and every safety official in the nation concentrated on ways and means of making street and highway travel safe for America's 30 million motor vehicles. The Firestone Tire & Rubber Company announces the introduction of a new motoring safeguard—the tire X ray

This new application of the X ray, a bene

Looking through a tire

factor of man ever since its discovery in 1895, will enable car owners to checkmate most of the 40 million flats that are now occurring annually. With this equipment only a few minutes are necessary to X ray a set of tires. The operation is simple. No pictures are taken The owner looks directly through his tires without removing them from the wheels.

In an experimental test, engineers X-rayed the tires on 100 automobiles. The tire X-ray revealed that 99 percent of these cars-carried one or more hidden tire dangers. A further investigation of 2000 worn tires produced 2049 nails and tacks, 2099 pieces of glass, and 2197 pieces of rock and small stones which had become lodged either in the tread or deeper in the body of the tire. In addition, a considerable number of tires showed breaks in the cords as well as other defects that would have eventually resulted in a flat, or possibly a blowout.

Detection of these under-cover hazards with the Firestone tire X ray is a simple procedure. The automobile is elevated several inches above the floor and the tire X ray is rolled under one wheel Protective flaps are adjusted to confine the rays to the section of the tire that is being inspected. The operator turns a crank which rotates the entire wheel When any foreign object or defective section of cord is revealed, it is immediately spotted, automatically marked, and the inspection continues. Once located, the foreign objects are quickly extracted with special tools after the tire X-ray inspection has been completed.

In addition to its value as a safety factor,

the use of the tire X ray adds mileage life well beyond the normal expectancy of a tire that does not receive X-ray inspection. Glass and nails in the tire body, agitated by every revolution of the wheel, weaken the body structure After miles of travel in this condition the tire is permanently injured, even though the tube itself may have remained intact. Thus tire X ray is not only a life saver. It is a money saver

RESEARCH

ON industrial and engineering research there was expended during 1938 about \$180,000,000, according to an estimate by Dr. W. A. Hamor, of the Mellon Institute.

PEELING POTATOES BY FLAME

DRUDGERY and waste are being taken out of peeling potatoes by a new process in which the tubers are exposed for a few seconds to a flame temperature of 1750 degrees, Fahrenheit. This almost instantaneous heating of the peel blisters and chars it so that a high-pressure water spray can remove it completely from the potato. Eyeand blemishes must be removed by hand subsequent to peeling. This process is being applied to potatoes and other vegetables for hotels and restaurants using large quantities—D. H. K.

WIRELESS RECORD PLAYER FOR RADIOS

DEVELOPMENT of a wireless record player which combines in compact form the virtues of a fine phonograph and the flexibility and control advantages of the modern radio receiver has been announced by the radio division of the General Electric Company

The new record player was designed to meet the demands of the modern home for a musical instrument which will play with-

Self-contained wireless record player for use with any radio receiver

out interruption the outstanding recordings of the day. No sound issues from the cabinet of the record player itself during its operation; the automatic electric sound reproduction and control devices of an existing radio receiver are employed, thus utilizing the owner's previous investment to greater advantage. Despite this use of the home radio receiver, however, there is no wired connection between radio and record player, a fact

which makes the performance of the device almost uncanny to the observer.

This accounts also for the flexibility of the record player since in practice it can be used effectively with any radio within hearing distance. From a single location in the home, where it is plugged into the household circuit, the music from records being played can be heard from a receiver in the central hving room, or from small sets in a play-

With no connecting wires

100m, or in upstairs bedrooms, or on an outside terrace.

Most radio receivers built by General Electric for 1939 are equipped with a special key, or button, which is pressed when the record player is in operation. This makes available an unoccupied section of the broadcast band. On other sets, however, it is only necessary to set the dial at a "dead" spot in the broadcast band, with the power on. The record player acts as a small broadcasting station, transmitting the electric impulses represented by the record to the radio receiver, whence they emerge as sound Provision is also made in the new record player for the attachment of a small microphone, enabling users to "broadcast" to their own radio, from which their voices emerge.

INEXPENSIVE AIR FILTER

DESIGNED primarily for removing pollen from air, but equally effective for removing dust, soot, and lint particles, is a new low-priced air filter offered for home and office by Norris Industries, Inc. Tests in a hospital room show a pollen count of 1159 outside to be reduced to three per cubic yard inside.

The purifier comprises a weatherproof casing with two Burgess filters, and fittings to make it adjustable to all but casement windows. By using any ordinary 10-inch household fan, which is placed inside the casing, 200 cubic feet of air per minute are driven through the filters. Through a unique arrangement of louvres in the sides of the casing, air from the room is re-circulated and cleaned. Thus 125 cubic feet of fresh air are drawn from the outside and filtered, while 75 cubic feet are being re-filtered to maintain dust- and pollen-free surroundings. Unless operating in very dirty surroundings, filters may last a season, but can be replaced economically.

TEMPERATURE CONTROLLING METAL

A NEW alloy of iron, nicked, shromium, and silicon developed at the Battelie Memorial Institute has the remarkable prop-

erty of losing its magnetism at a definite temperature which can be predetermined between 1100 degrees, Fahrenheit and —150 degrees, Fahrenheit. At the critical point, where the metal loses its magnetic properties, it goes through a phenomenon to which the word "shivering" has been applied; when this occurs it can be utilized to control electric circuits or operate other temperature controlling devices. The temperature at which this change occurs in the metal is established by the proportion of the various constituents in the alloy.—D. H. K.

Nozzle for All Classes of Fires

A NEW type of nozzle that is especially desirable for general use on fire-hose lines because it permits the use of water in large quantities for extinguishing all classes of fires, including fires in oils and in live, high-voltage electrical equipment, has been developed by American-LaFrance-Foamite Corporation, manufacturers of fire protection equipment, Elmira, New York

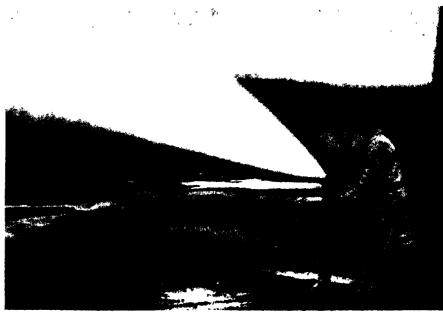

This new device, which is known as the Poweron nozzle, discharges water in a discontinuous spray that is especially effective for fire-fighting purposes and does not conduct electricity. It cannot be adjusted to throw a solid stream of water Tests conducted by the Underwriters' Laboratories showed that the nozzle is suitable for use on equipment carrying current at voltages as high as 250,000

The Poweron nozzle is similar in size and appearance to the ordinary fire-hose nozzle and can be attached to any standard fire hose. Its special form of discharge, besides being more effective than a solid stream of water, forms a water curtain between the operator and the blaze. The nozzle is non-adjustable.

TUNNEL LINING

THE Chain Belt Company, of Milwaukee, recently shipped one of two Rex Tunnel Lining Machines for concreting operations on the Gunpowder Falls Montebello Tunnel which is part of the water supply system for the city of Baltimore. This tunnel will extend a total length of seven nules with an inside diameter of 12 feet and will require about 70,000 cubic yards of concrete. There will be two principal shafts from the suiface through solid rock to the tunnel, each about 200 feet deep and spaced at two-mile intervals from Baltimore.

To handle this concreting job, the company designed and constructed two tunnel lining machines. These units are modeled along the general line of the Rex tunnel machines used on the Metropolitan Water Dis-

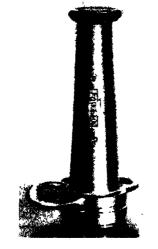

Left The new spray nozzle that holds great advantages for fighting any fire. Above: A demonstration that shows the type of spray

car through a lever and cable arrangement which is part of the mixer car.

The machine is powered for DC, operation, and all of the controls are conveniently placed to operate from a platform on the mixer car.

The two complete tunnel lining units will be operated independently of each other inside the tunnel and each unit will have a fleet of 15 batch cars serving it. The contractor plans to div-batch his aggregate and cement on the surface, and drop the batch down a pipe through the shaft and through a transfer bin into the batch cars

trict project in Southern California, with, however, some very definite modifications to adapt the equipment to work in a 12-foot

unnel.

There are two separate car—a mixer car weighing approximately 18,000 pounds and a Pumperete car weighing approximately 16,000 pounds. Each car is on flanged wheels with individual traction drive to operate on 36-inch gage tracks. The two cars are designed to work close-coupled as shown in our illustration.

At the extreme right is one of the batch cars which will be used to charge the mixer. The batch body has a capacity of two 1¼-cubic yard batches. As the car is backed up to the mixer, two arms from the mixer car engage the body and hoist it into charging position. The body is lifted from the batch

MILK

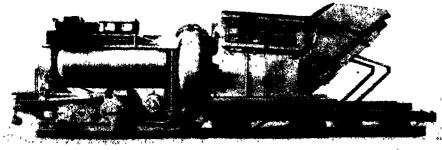

MORE than 100 billion pounds of milk are produced and consumed in the United States each year. The average in recent years has been 106 billion pounds.

EIGHTY-ONE CENTS' WORTH OF DIRTY BUSINESS

BECAUSE a user with a laudable curiosity complex wanted to know how much it cost to operate a vacuum cleaner for a year, approximately 200 housewives were called upon to answer her and the figures were recently revealed by R. F. Sambleson, commercial engineer of General Electric's vacuum cleaner section at Bridgeport, Connecticut.

The average cost of power in the United States is roughly five cents per kilowatthour. A regular floor type cleaner uses .325 kilowatts, and a hand type only .200 kilowatts. The G-E engineers figured 50 hours of actual cleaning a year as a reasonable basis for their computation, which makes the operating cost of the floor type 81 cents a year, and that of the hand type 50 cents.

Then, just to check their usage figures, 200 cleaners were put into actual home use for a year, with timeclocks on them to measure the time during which the motor

The tunnel lining unit is made up of two separate cars as described

Above: Cherry trees, growing in incubator bottles under aseptic conditions, will later be transferred to pots. Below: Incubated peach seedlings after transplanting

was running. The average figure turned out to be only 33 hours, which would make the annual operating cost a third lower than previously supposed. Either this is a tribute to the efficiency of the cleaner, in Sambleson's opinion, or husbands should begin checking up on the time-bonoied statement that "woman's work is never done." In either case, 81 cents is the top figure, and that wouldn't even buy a good broom.

SHRINKPROOF WOOLENS

W OOLEN blankets made proof against shrinkage by treatment with a solution of sulfuryl chloride in dry cleaning solvent have been recently put on the American market. The treating process is English and is known as the Hall process

Conducted under rigid control, the simple treatment of woolen goods by immersion in a sulfuryl chloride solution of proper concentration acts on the serrations of the individual fibers and makes the fabric permanently non-shrinkable. After treatment, the fibers are stronger, slightly whiter, and somewhat softer than untreated wool. Several manufacturers are offering woolen goods which can be guaranteed against shrinkage so long as the treatment given the fabric does not destroy the fibers themselves—D. II. K.

GROWS FRUIT TREES IN "INCUBATORS"

DIFFICULTIES encountered in the course of the fruit-breeding work in progress at the State Experiment Station at Geneva, New York, particularly with respect to developing early ripening varieties of the stone fruits, have given rise to a so-called "incubator" method of handling the embryos of fruits that would otherwise be lost. "In cubator" fruit trees have reached maturity and are now bearing fruit on the Station grounds.

A brief popular description of the men-

bator method of growing fruit trees was given by Dr. H. B. Tukey in a recent issue of Farm Research, the Station's quarterly magazine. "Breeding fruit trees by 'incubator methods,' as it has been called," he says, "consists in removing the embryo from the mother fruit during the growing season and placing it in an 'incubator' bottle under aseptic conditions, properly nourished with various salts and a sugar supply, with the result that a new seedling fruit tree is produced which is a potential new variety." By this method the Station fruit breeders have saved many seedlings which might otherwise have died.

The method has proved most valuable in saving seedlings from crosses of early ripening peaches, cherries, plums, and apricots. Heretofore, most of the embryos of crosses of very early ripening varieties of these fruits have failed to develop properly and much or all of the cross has been lost. By removing the embryos at the correct stage of development and nursing them along in the incubator bottles, the Station now has a number of potential new varieties of these fruits well along the road to maturity, while some few of them are actually beginning to bear fruit

The method has found another unexpected but very useful application in the nursery industry, as a germination test of fruit tree and forest tree seeds. By this method the percentage germination of the seed can be determined within seven to ten days as compared with a period of several months under ordinary conditions. It is also supplying much valuable information on the growth habits of fruit embryos which will doubtless prove helpful to plant scientists.

ALCOHOL IN ICE CAPS

TO simplify nursing routine by eliminating numerous time-consuming operations, one large hospital is standardizing on the use in ice caps and collars of a 10 percent alcohol solution in place of the conventional cracked ice, according to the American Jour-

nal of Nursing. The solution freezes at minus 4 degrees, Centigrade.

Each cap is filled with 500 cubic centimeters of a 10 percent alcohol solution and, the article states, takes from 60 to 90 minutes to freeze in electric units employed by the hospital. Used ice caps are washed with soap and water, dried and then returned to the freezer. It is not necessary to remove the solution, according to the article.

Tests over a five-year period in an 18-story surgical building, with an average census of 250 patients and a five-room operating suite, are said to have convinced authorities of the economy of the measure.

The mixture produced by the freezing of the solution is described as firm but easily broken up by hand to make the cap conform more readily to body contours.

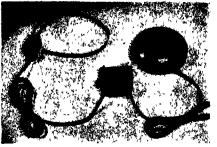

LAMPS

FOUR fifths of a billion—800,000,000,000—incandescent lamps were sold in the United States during the year 1938, Of these, 485 million were of the everyday kind.

MINIATURE TELEPHONES AID HEARING

As a result of many years of research and development work in artificially reproducing speech, Bell Telephone Laboratories have perfected a new type of hearing aid, known as the Ortho-Technic Audiphone. The newly perfected device, so small it can be concealed on the person, is actually a miniature telephone of the most improved type

After the sound waves are picked up by the efficient "transmitter," they are amplified

A typical Audiphone combination using a bone conduction receiver. Below: Ear pieces for air conduction receivers are supplied in universal types or may be molded to order to suit the individual ear

to a suitable strength and led into a miniature "receiver," which repeats them at the point where they may best actuate the organs of the inner ear. For this purpose, it may be advisable to locate a diminutive receiver in the outer ear, or it may be more advantageous to locate it against the head immediately behind the ear, where it will transmit the sound vibrations through the bony structure to activate the hearing organs within. This, and selection of the proper units to complise the most effective Orthe Testings.

For MEN

who want to become independent in the NEXT TEN YEARS

In the Spring of 1949 two business men will be sitting in a mid-town restaurant. "I wonder what's going to happen next year," one of them will say. "My business is fine now-but the next few years are going to be hard ones, and we may as well face the facts."

The man across the table will laugh.

"That's just what they said back in 1939," he will answer. "Remember? People were looking ahead apprehensively-and see what happened! Since then there has been the greatest growth in our history-more business done, more fortunes made, than ever before. They've certainly been good years for me."

He will lean back in his chair with the easy confidence and poise that are the hallmark of real prosperity.

The older man will sit quiet a moment and then in a tone of infinite pathos:

"I wish I had those ten years back," he will say.

• Today the interview quoted above is purely imaginary. But be assured of this-it will come true. Right now, at this very hour, the business men of America are dividing themselves into two groups, represented by the two individuals whose words are quoted. A few years from now there will be ten thousand such luncheons and one of the men will say:

"I've got what I wanted." And the other will answer:

"I wish I had those years back." In which class are you putting

yourself? The real difference between the two classes is this-one class of men hope vaguely to be independent sometime; the other class have convinced themselves

CONTRIBUTORS TO THE COURSE

Business Address

Business Position

In Canada, address Alexander Hamilton Institute, Ltd., C. P. R. Bidg., Toronto, Can. Audiphone combination, is decided after an analysis of the subject's hearing acuity by means of the Audiometer test.

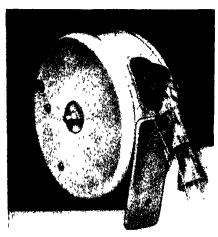

The Audiometer is an instrument specially designed and built to analyze an individual's hearing acuity. Through a test by this instrument, comprehensive information is obtained regarding the relative response of the individual's hearing organs through air conduction and bone conduction.

The new Ortho-Technic Audiphone operates efficiently in any position, regardless of whether the wearer is reclining, sitting, or standing The user need not be confined to conversations with an individual, for he may participate freely in group conversations. By manipulating the convenient "volume" control, he may enjoy the loud music of a brass band close at hand or he may understand completely what is being said by a person speaking in normal tones on the opposite side of an ordinary sized room. Because it consumes less power than previous designs, the new device does not require replacement of batteries as often, which makes it more economical in operation

AUTOMATIC REELS FOR ELECTRIC CORDS

A MODERN and inexpensive solution to the old problem of daughing, unsightly extension cords on electric appliances and electric equipment is made possible in the new Cordomatic—automatic cord control reel—just announced by The Cordomatic Division of the Vacuum Cleaner Corporation of America.

Made in a variety of sizes and designs for either external or concealed mounting. Cordomatic reels are complete, fully enclosed,

No more twisted electrical cords

self-contained units, ready for installation. They maintain the exact needed cord length at all times, eliminate cord wear, keep castors from damaging the cord, stop kinking and tangling and avoid danger of accidents from dangling coils. The cord is paid out as required and then is retrieved automatically and wound inside the metal container where it is out of sight, out of the way.

BASEMENT GREENHOUSE

A BASEMENT, glass-less greenhouse which holds interesting possibilities for profitably utilizing basement space in homes in congested areas, has been designed by Professor Alex Laurie, of Ohio

State University. It is not intended to supplant the familiar greenhouse, but merely to serve as a propagating house and for "finishing off" plants which have been brought almost to the blooming state in pots. A series of tests were made to determine its fitness as a propagating house and cuttings of carnations, geraniums, chrysanthemums, and many other varieties

In a basement

were successfully grown in clean, sharp propagating sand

For those who might wish to build a basement greenhouse as a propagating house, the construction is of the simplest Walls of pressed wall board are nailed on each side of two by four partitions, the dead space between the double walls acting as an insulating area against both heat and cold The inside walls of this simple greenhouse are painted white to reflect the maximum of light from the 100-watt Mazda lamps which are installed two feet apart and suspended two feet six inches above the propagating bench. These are operated 12 hours a day by automatic clock, Electric soil-heating cable is installed on the benches and is thermostatically controlled to maintain the soil temperature at 73 degrees, Fahrenheit.

A fresh-air inlet from outdoors is installed at floor level with an exhaust fan at the ceiling. A thermostat control actuates the fan when the temperature rises above the desired level and stops it when the temperature drops to normal. Frequent syringing of the plants is necessary in order to maintain humidity at a desirable dew point and, in addition, trays of water are kept for this reason under the benches—(F. Greeves-Garpenter)

THRESHOLD TREATMENT OF WATER

RECENT investigations initiated to prevent caking in valves and distributing lines of irrigation systems, caused by the addition of small amounts of ammonia to hard water, have proved the high value of minute doses of sodium hexametaphosphate as a preventive. This treatment, called threshold treatment because so little water softener is used, has not only permitted the economical distribution of ammonia as fertil-

her in irrigation water supplies but has shown the way to prevent incrustation in other water systems.

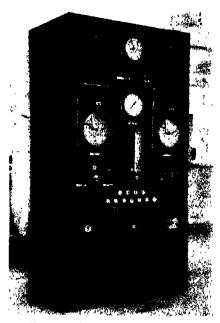

As little as one or two parts of the metaphosphate in a million parts of water effectively prevents the precipitation of calcium carbonate and other salts in water systems. The development of the threshold treatment is so recent that new applications are being found daily. In Ohio, the water supply of a city is being treated to prevent incrustation of the filters in the softening plant and of the distribution system throughout the city In Illinois, a river which flows continuously through the condensers of a large commer cial distillery is subjected to threshold treat ment so that the condensers will not scale up. In Texas, where the condensers on the cracking stills used to plug up solid in one month, the use of metaphosphate has prevented scale, allowing the units to run indefinitely. In state after state where hard water supplies are encountered, the railroads and the steam power plants are using this phosphate glass in what seem like ridic ulously small amounts to avoid operating difficulties resulting from calcium carbonate

The development of the uses of sodium hexametaphosphate in the conditioning of water is purely an American achievement, although this substance was first studied by the British chemist, Thomas Graham, over a century ago—I) H K

CO-ORDINATED PROCESS CONTROL

INDUSTRIAL instruments give close control for carefully planned processes Bristol's system of co-ordinated process control is an automatic machine which controls process operations, where instruments—in dividually operating to control such process variables as temperature, pressure, liquid level, flow, humidity, and motor or machine speed—are co-ordinated and interlocked into a single control unit so that they per form operations in successive steps and proceed in the proper sequence as required by the process.

The system is exceedingly flexible and is, therefore, used to control a number of dif-

For co-ordinated process control

ferent types of manufacturing processes. Those already in operation may be placed under supervised control or those newly developed and previously perfected in the laboratory and pilot plant may be put into automatic production on a full-scale basis. Such control prevents deviation from the original plan and eliminates the chance for error resulting from manual supervision.

This new system of co-ordinated process control consists essentially of a multiple cam eyele controller, or "Mechanical Brain," which controls through the medium of compressed air and by means of leakless pilot valves and cams. Around this cycle conttoller, standard recording and controlling instruments are built to operate valves (all sizes up to large gate valves), pumps, blowers, dampers, and electrical equipment. By means of the cycle controller, the operation of these instruments is controlled to a time program, so that the devices to control such variables as time, pressure, liquid level, flow, humidity, speed, and mechanical motion, may be operated automatically, according to the schedule found to be responsible for the best over-all results. In this way the system provides for a carefully planned machine, built in the form of a suitable panel board, to control, automatically, involved processes where the human element in supervision may best be eliminated

Molasses as Fertilizer

W ASTE molasses is being used as a source of nitrogen for fertilizing Hindu soils. Good results have been obtained using dosages as high as 30 to 40 tons per acre.

HYDROGEN

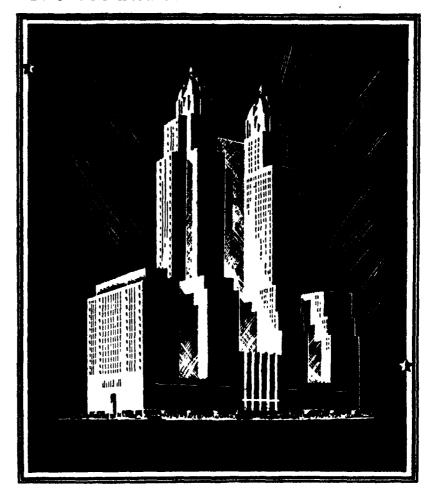

BECAUSE it is only about a tenth as heavy as air, hydrogen, used inside the casings of great electric generators to cool them, reduces the windage, or friction, of their giant rotating shafts to one tenth that of air. Hydrogen is thus a vital factor in increasing power efficiency.

OLD AGE CAN WALK— CAN'T SPRINT

The inability of an old man to sprint 100 yards although he may be able to walk all day as well as in his youth is due in part to loss of capacity to accumulate factic acid in exercise, according to Dr. David Bruce Dill of the Fatigue Laboratory of Harvard University.

Lactic acid in the body, Dr. Dill explains, is a fuel for muscular contraction which has sometimes mistakenly been spoken of as a "fatigue substance."

"It may be that the heart has a greater capacity for work in severe exercise than ordinarily because of the high concentration of lactic acid in the blood pouring through it," Dr. Dill continued. "Dr. Robert Johnson in the Harvard Fatigue Laboratory has found that lactic acid, however rapidly it passes out of muscle cells, enters the red cells of the blood very slowly; so slowly that after one or two minutes of severe exercise nine tenths of the blood

THERE IS ONLY ONE "WALDORF"

Its towers, sharply etched against the sky, are modern as tomorrow...yet its tradition of hospitality goes back to a grand and spacious age.

Its glamorous restaurants, favorite gathering-places of metropolitan society, are vibrant with music and galety... while above, its rooms are star-quiet in the night, peaceful as the hills of home.

Its guests include the great ones of a busy world . . . and the quiet, unassuming people who make that world go 'round.

THE WALDORF-ASTORIA

PARK AVENUE . 49TH TO 50TH STREETS . NEW YORK

The Editors Recommend

Best Sellers in Science

(Revised List)

1. SOILLESS GROWTH OF PLANTS—By Carleton Ellis and Milton W. Swaney. Complete information, popularly presented, regarding the problems and difficulties of tank farming. Formulas for chemicals and instructions for preparing tanks and other containers are given Recommended to both experimenters and commental growers.—\$2.85 postpaid.

2. PROCEDURES IN EXPERIMENTAL PHYSICS—By John Strong, Ph.D. With four other scientists, Dr. Strong has assembled a wealth of useful data of a wholly practical kind for the constructor, experimenter, and skilled craftsman. Many lucid illustrations—\$5.10 postpaid

\$5.10 postpaid

3. SCIENCE EXPERIENCES WITH HOME EQUIPMENT—By C. J. Lynde.

A book of 200 simple home tricks based on physical laws, each experiment being illustrated and its principle explained - \$1.45 postpaid

and its principle explained - \$1.45 postpaid
4. EAT AND KEEP FIT—By Jacob Buckstein, M.D.
A popular treatise on foods, vitamins and cognate subjects, with instructions for dieting
- \$1.10 postpaid
5. KNOWING YOUR TREES—By G. H. Collingwood. Fifty common trees of the United States each tree discussed in a two-page spread, with pictures of a typical tree, of foliage or fruit, and of the trunk, and a drawing of the 1 nited States showing natural range of the tree—\$110 postpald

6. THE ENGINEER'S SKETCH-BOOK OF MECHANICAL MOVEMENTS—By

Thomas Walter Barber.

Working drawings of practically every conceivable movement, device, appliance, and continuate employed in the design and construction of machinery for every purpose Acarly 3000 illustrations - \$4 35 postpaid

7. SUNDIALS—By R. Neuton and Margaret L. Mayall

DUNDIALS—BY R. Neutron and Margaret L. Mayall
 The best book on sundials A practical work by a landscape architect and a professional
 astronomer illustrated —\$2 10 postpaid.
 A MARRIAGE MANUAL—By Hannah M. Stone, M.D., and Abraham Stone, M.D.
 A practical guide to sex and marriage covering fitness for marriage, mechanism of re production, prevention of conception, and similar vital subjects. Answers questions most
 often asked these authors by their consultants—\$2.50 postpaid
 THE ART AND SCIENCE OF MARRIAGE—By Esther B. Tietz, M.D., Ph.D.,
 and Charles K Waishart Ph.D.

9. THE ART AND SCIENCE OF MARRIAGE—By Esther B. Tietz, M.D., Ph.D., and Charles K. Weichert, Ph.D.

A well-balanced, authoritative study of the body and its functions, including the reproductive system, and a practical discussion of courtship and marriage Recommended especially for engaged comples—\$2.60 postpaid

10. SCIENTIFIC METHOD—By F. W. Westaway.

An omnibus of the scientific method for those who wish to learn to think straight Clearly written for the scients person who, after reading it, will feel that his thinking processes have been inclted down and recast—\$3.85 postpaid

11. LIGHTING IDEAS IN PHOTOGRAPHY—By William Herrschaft and Jacob Deschin, Editor, "Camera Angles," Scientific American.

Complete photographic lighting for the amateur, glving fundamentals and methods, fully portrayed by descriptions, diagrams, and examples.—\$2.85 postpaid

12. COLOR PHOTOGRAPHY FOR THE AMATEUR—By Keith Henney.

All the information you need in order to take up this branch of photography or to get better results in it Characteristics, costs, (te of various methods of color photography for the smatter.

\$3.60 postpaid

amateur \$3 60 postpaid

13. MAKE IT YOURSELF—By Julian Starr, Jr.

An amateur Craftsman's book with instructions on how to make things at home with tools, including chairs, tablies, children's playhouses, cabinets, numerous games, weather vanes, birdhouses, breakfast sets, and so on Illustrated \$2 60 postpaid

14. THE HANDY MAN'S HANDBOOK—By C. T. Schaefer.

Pourth edition of a very popular book—a practical manual on the use of tools and how to do all-norts of odd jobs around the home \$1 10 postpaid

15. ARMATURE WINDING—By David P. Moreton, Carl H. Dunlap, L. R. Drinkall, Construction, winding, and repairing of A C and D C motors and generators, all steps clearly shown in photographs and drawings Practical—\$2.10 postpaid.

16. ATOMIC ARTILLERY—By John Kellock Robertson.

Electrons, protons, positions photons, neutrons, and cosmic rays in plain language Also

Electrons, protons, positions photons, neutrons, and cosmic rays in plain language Also transmitiation of the elements and manufacture of artificial radioactivity.—\$2.35 postpaid

17. TRAINING YOUR DOG—By Carl Spitz

Workable methods for training dogs Recommended for all dog lovers. Illustrated—\$2.60

18. SHIPS OF THE WORLD'S BATTLEFLEETS-Edited by Pay-Lieut. Comdr.

18. SHIPS OF THE WORLD'S BATTLEFLEETS—Edited by Pay-Lieut. Comdr.

E. C. Talbot-Booth, R.N.R.

Essential facts regarding the principal ships in the navies of the important powers, with details of construction, silhouette drawings, and a large number of photographs—\$1.60 postpaid

19. THE MYSTERIOUS UNIVERSE—By Str James Jeans.

Covers a remarkably broad territory, touching on everything new in modern physics, astrophysics, and cosmology Many men of science now are leaning toward a non materialistic interpretation of the universe and Jeans is one of these—(Formerly \$2.40.) Now \$1.10 postpaid

20. THE ROMANCE OF ASTRONOMY—By Florence A. Grondal.

The author writes for the average reader who would like to know more about the stars and the planets. Her book brings to life the facts of astronomy through picture and story. Illustrated with striking photographs and diagrams—(Formerly \$5.00.) \$1.55 postpaid.

21. SNAKES OF THE WORLD—By Raymond L. Ditmars,

Probably the most readable, attractive and extensive discussion of the subject yet offered to the general reader. It discusses the more than 2000 different kinds of snakes. A superb collection of illustrations.—(Formerly \$6.00.) \$2.10 postpaid.

lactic acid remains in the plasma, or fluid part of the blood.

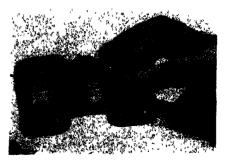

"The capacity to accumulate lactic acid in exercise is lost in old age. A man of 70 may have one half the capacity for carrying on work in a steady state which he had in his prime, but his capacity for work carried on after the supply of free oxygen in the blood is depleted is almost lost. There are many illustrations of this-many men of advanced years can walk all day as well as in their youth, but sprinting for 100 yards would be impossible. De Mar at 49 ran the marathon as well as at 22, and Cunningham runs the mile at 29 better than at 22, but who knows a successful sprinter as old as 29?"

VEST POCKET SPORT

GLASS

NEW vest pocket sport glass, as casy L to carry as a cigarette case, has been designed by Bausch & Lomb Optical Company for use at all outdoor sports or at the opera.

The new glass is of 3-power and rectangu

lar in shape, designed to afford an exceptionally wide view rather than a high one. This makes it particularly suitable for all sports, since the width of the field is 452 feet at 1000 yards. It weighs but six ounces.

SYNTHETIC WOOL

Vulnerable

THE enthusiasm that has been shown in various countries for synthetic wool made from the casein of milk has been dampened by the discovery that certain bacteria will destroy casein even after it has been woven into a garment. Synthetic wool garments require no moth balls to protect them, since moths do not attack casein. Synthetic wool, however, may be destroyed by bacteria, against which moth balls are no protection. Obviously the present fabrics used in Italy which are made up of half wool and half synthetic wool are vulnerable to both attacks .-- D. H. K.

"EVERYTHING FLOWS"

TEW clues to the underground mechanism causing earthquakes, mountain formation, and other geological phenomena have been found by a Harvard physicist in the action of rocks under tremendous laboratory pressures.

David Griggs, junior fellow in geophysics, has utilized the high-pressure equipment of Prof. P. W. Bridgman to duplicate the pressure conditions in the earth's outer crusta granitic layer extending down 30 to 50

Under the high confining pressures, which

一、一口,在5点相,其外是自由人

reached a maximum of about 300,000 pounds per square inch, it was found that limestone could be made to flow. A small block of it was compressed 35 percent in length without shattering. Contrary to past geologic beliefs it was found that, under high pressure, rocks will not flow indefinitely but will break if deformation is carried far enough.-Science Service.

LIFE-SAVING BELT

AN inflatable, chemically-operated rescue belt has been developed by Lyf-Boy Corporation. This consists of a belt, a part of which may be inflated with a gas from a self-contained chemical. In use, the belt

Life-saving belt that is fastened around chest and quickly inflated

is fastened around the chest of the drowning person by the lifeguard, who then squeezes the belt to start the inflation, Buoyancy is thus provided for the victim so that the lifeguard may tow his charge ashore by means of a hair-carry or a chin-carry.

Squeezing the belt causes a weak acid solution to be sprayed on a small quantity of bicarbonate of soda, resulting in the evolution of the inflating gas.

OZONE-RESISTANT RUBBER INSULATION

PAILURE of rubber-insulated electric wires and cables frequently results from the attack of ozone in the atmosphere. To prevent this, a layer of rubber free from sulfur, and hence unvulcanizable, is being placed on the outside of the ordinary rubber sheet and is said to protect it from ozone damage. Electric discharge, due to leakage. forms ozone in the air; apparently by preventing this, the new method prolongs the life of rubber insulation.—D. H. K.

CAN TRAFFIC LIGHTS BE IMPROVED?

THE excellence of the type of traffic sig-I nals adopted in The Hague is recommended for consideration outside of Holland. The signal consists of a large circular surface protected by a hood. On this surface are 12 concentric vacuum lights—six neon tubes for red and six mercury vapor tubes for green. When all six red rings are lighted, traffic is stationary. As time passes, one ring after another becomes extinguished, and as the last disappears the green rings flash on and traffic moves. The six green rings then

De Luxe Library Editions of SCIENTIFIC AMERICAN

Make them yourself, protect and preserve your copies with a

PERMO LIFETIME BINDER It holds a year's issues

So MANY readers preserve their copies year after year and have asked for binders that, after thorough investigation of binders, the editors of Scientific American found a type that is most satisfactory, considering cost, ease of handling, and durability. It holds a full year's issues (12), has an efficient patented lock; is strong and durable; and is covered with a rich, pebbled, red leatherette beautifully stamped in gold. Magazines are bound in with a snap and are held positively in place; no punching necessary. In ordering, state what year (1938, 1939, etc.) is to be stamped in gold on the backbone.

Each \$1.50 postpaid in continental U. S. (\$2.00 postpaid elsewhere)

Scientific American, 24 West 40th Street, New York

successively disappear and the cycle is repeated.

Such a system possesses this very important feature: both automobile and pedestrian traffic can judge the time during which a particular signal will operate. Motorists see when to prepare to go, and the pedestrian sees how much opportunity remains for crossing. There is only one illuminated area instead of three, and there is no amber light to be abused.—Highways and Bridges Magazine, London.

A traffic light of similar principle was recently demonstrated in Massachusetts. This signal consists of an aluminum encased circle of 16 bulbs, 15 white and one red. The lights indicate the number of seconds before the light is to change. It is reported that the signal "circle" may be attached to any ordinary traffic signal.

ELECTRICAL POULTRY FARM

N the chicken farm of Charles F. Wendig, near a swank colony of artists and writers at New Hope, Pennsylvania, electricity is now at work waking chickens in the morning, keeping the young warm, heating their drinking water, providing them with a 12-hour-light day, mixing their feed, sterilizing their air, cleaning their eggs and grading them, and putting them to bed at night. This is but a partial inventory of electric wired helpers" which have transformed the Wendig enterprise into the first Westinghouse Electric Poultry Proving Farm

DYLING WITH GOLD

A NEW process of depositing gold on fabrics, which resembles the ordinary dyeing process, has recently been developed. The fabric is dipped in a solution containing a complex organic compound of gold (trialkylphosphine aurous chloride) and on heating becomes coated with a thin, even deposit of gold left by decomposition of the dye—D H K

THE ENGINEER: A DEFINITION

"AN engineer is one who, through application of his knowledge of mathematics, the physical and hiological sciences, and economics, and with aid, further, from results obtained through observation, experiences, scientific discovery, and invention, so utilizes the materials and directs the forces of nature that they are made to operate to the benefit of society. An engineer differs from the technologist in that he must concern himself with the organizational, economic, and managerial aspects as well as the technical aspects of his work."—Dr. Karl T. Compton.

BETTER SWITCHES

E NGINEERS have long recognized the unsatisfactory operation of switches with breaking points exposed to the air. Circuits carrying heavy loads are difficult to open because the arc and high temperature causes pitting of the contact points. On circuits carrying lighter loads, dust and cor-

VITO BELT for 10 days at our expense!

"CORPORATION CONTROL" by the Vito Belt Method is popular with successful executives. "Bay Windows" are a relic of the past... why not look trim-waisted, ready for action... a modern figure in a modern world? Take care of that ugly paunch in the safe, easy way—with a VITO BELT!

SAFE GIRTH CONTROL

SAFE GIRTH CONTROL

Exercise may strain your heart . . . diets and drugs may be dangerous. Yet no man wants to appear ridiculous. The answer is the comfortable Vitto Belt that makes you appear a smaller, streamlined model of yourself the minute you put it on. We want YOU to test it . . . wear it . . . for 10 days, at our expensel Then you will see for yourself what a well-set-up, military carriage it gives you . . . what a change it makes in that bulging pypofie! If it does not do everything you expect. . . it will cost you nothing!

SUPPORT WITH COMFORTS

The Vito Belt is made of pure Para rubber molded to give maximum support without "siding up". Hundreds of perforations give ventilation, helping to evaporate the body moisture. The special lace back takes care of any change in size.

SAGGING MUSCLES MAY CAUSE TROUBLE!

Waistline fat often stretches abdominal muscles, allowing digestive organs to drop. Support them with the Vito Belt and help them function normally.

MAKE A 10-DAY TEST...AT OUR EXPENSE!
You'll never know what amazing results are possible until YOU wear the Vito Belt. You owe it to yourself to take advantage of our 10-day Trial Offer. Send coupon for details TODAY!

HAMILTON BELT CO., INC. 173 Hill Street, New Haven, Conn. Gentlemen: Send me FREE illustrated folder plain envelope, describing the Vito Belt giving full details of your 10-day Trial Of	r, in and Fer.

rosion are the enemies of the points. When the first mercury switch appeared, it seemed to be the solution of these problems. In principle, it controlled circuits with sealed contact points preventing exposed arcing. Also, since each contact was made through fresh points of mercury that was sealed to prevent corrosion and dirtying, such a switch should last indefinitely.

However, ordinary mercury switches had many faultmental prevented their general use. The use of a metallic envelope together with a non-flammable and non-explosive liquid

Metal shell mercury switch

fill in the Durakool metal mercury switch overcoines the faults of the usual mercury switch

Durakools are perfectly cylindrical so that they may be turned through a full 360 degrees on their long axis without changing their operating characteristics. That is to say, any side up is the right side up. This is not true with ordinary mercury switches Also, the principles in these new mercury switches allow them to be built and used in sizes up to 200 amperes. This is by far the largest mercury switch ever commercially available so far. They are being rapidly applied to an astonishing variety of mechanical equipment ranging from tiny humidity controls to gigantic concrete mixers used on the Conchas Dam. There are at present about 5500 known applications where Durakool mercury switches will serve satisfactorily, including control of many kinds of machines, pumps, clocks, scales, com-operated machines, and many other devices

FIRE-WALKING

(Continued from page 138)

fairly quickly, and stepped off at the side, stating that the fire was too shallow.

Afterward, however, he walked the same fire three more times, but with fewer and quicker steps. His feet were again examined and found uninjured. Thirty minutes later there was likewise no sign of blistering. He refused to walk again, the fire being "not to his liking."

At the suggestion of one of the physicists the "cotton test" was applied. Human flesh scorches at a lower temperature than cotton fabric, so some calico was wrapped around a wooden shoe last. This imitation foot was "walked" upon the embers and in a second the calico was scorched, while in two and one half seconds the cotton was burned through in several places.

Digby Moynagh, editor of St. Bartholomew's Hospital Journal, who was present, decided to try the feat and momentarily placed one bare foot in contact with the embers. "His foot tingled for a considerable time afterward," Harry Price states. Next he walked two paces on the embers but jumped out, said it was "hot" (1) and that his feet tingled. For some time he felt noth-

Unquestionably, the leading home generator of ultraviolet light. this marvelous lamp should not be confused with cheaper imitations The Hanovia Alpine Home Sun Lamp generates cleven powerful wavelengths covering the entire useful and beneficial range of ultraviolet light. It takes but a few minutes-after a snap of the switch-for a complete, invigorating, healthful ultraviolet sun bath Regular sun bathing under this lamp builds resistance against colds and common ailments, gives a ruddy outdoor appearance

ing further, but in 30 minutes blisters had formed on the soles of his feet. He had walked more quickly than Kuda Bux. As will be seen later, undue haste in walking on embers may result in unnecessary burns. Moynagh's weight was 168 pounds, that of Kuda Bux, 120. There is a suspicion that weight has some bearing on fire-walking and that a very heavy person should not attempt it.

For a second test of Kuda Bux, one ton of firewood, seven tons of oak logs, and a load of charcoal were provided. The trench was reduced to nine inches in depth, widened to six feet and, at the request of Kuda Bux, its 25 foot length was broken in the middle by a platform of earth, thus altering it to two 11-foot trenches in line, with a three-foot space between.

Eight days after the previous tests the second were undertaken. The wood was ignited and after a few hours the glowing embers just filled the trenches flush with the ground. "We spent the morning feeding the flames," Price states, "and by one o'clock the pits were a mass of red embers, radiating a heat sufficient to be distinctly felt at a distance of 65 feet on the leeward side of the trenches. The assistants and rakers were compelled to wear goggles and the rakers used shields constructed from the sides of packing-cases. "It was blowing half a gale and, as the wind swept across the fires, they were fanned almost to white heat, ash in the form of powder being blown in clouds from the surface of the fires."

The load of charcoal was then added and in 20 minutes was cherry red. Kuda Bux was examined by Prof. C. A. Pannett, also by the three physicists who were present, Dr T. E. Banks, G. Smith of the London School of Hygiene and Tropical Medicine, and C. R. Darling who was recommended by the Institute of Physics. A number of other scientists were present, some from the University Council. Prof. Pannett, after examining the feet of Kuda Bux, stated that the soles presented no unusual features. The skin was not callous, but soft. The feet felt cold to the hand, and a skin thermometer applied to the soles registered 93.2 degrees, Fahrenheit. The skin was very dry. The feet were then washed and well dried and a small square of zinc oxide plaster was attached to the sole near the arch, to permit observation of any possible effects on its fabric due to the fire.

Seven hours after the eight tons of wood had been lighted Kuda Bux made the first walk, covering only the first 11-foot section of the divided trench. This he did in 4.5 seconds by stop-watch and in four strides—deliberately, steadily, fairly quickly. The records taken by the physicists give approximately one half second during which each foot was in contact with the embers.

Afterward, Kuda Bux's feet were found to have a temperature of 93 degrees, alightly lower than before the fire-walk, probably because he had taken a few steps on the cool grass outside the trench, after walking the fire. His feet were in no way injured and the plaster patch was untouched except at the edges where loose fluff was lightly scorched. He then took four more strides on the fire but no injury was found either immediately or 48 minutes later when his feet were reexamined.

How hot was the fire over which Kuda Bux walked? The physicists responsible for the measurements used a thermo-couple and 14187,7

the temperatures were as follows: Surface, 430 degrees, centigrade, or 806 degrees, Fahrenheit. Body of the fire, 1400 degrees, centigrade, or 2552 degrees, Fahrenheitwhich is a white heat temperature; in fact, steel melts at slightly lower temperature than this. It was owing to the high wind on the day of these tests that the embers reached so intense a heat. In fact, Kuda Bux, after preparing to walk a third time, asked for five minutes' grace, and then said he could not do it again "Something inside me has broken. I have lost my faith and if I do it again I shall burn myself." He looked worred and nervous and Price did not press him to do the walk a third time. And, at that, Kuda Bux no doubt was using excellent judgment. For Dr. E. H. Hunt, who was present, and had seen ceremonial fire-walking in India, stated that the test was made under unusually severe conditions, such as the high wind making the heat intense, which would have deterred most fire walkers.

Digby Moynagh, the novice who had tried the feat on the occasion eight days before, next took two steps on the fire but stepped off the trench. He was examined by Prof. Pannett who reports that "the soles of his feet had numerous healing blisters on them. He acquired some more at the second attempt. His skin was moister than the Indian's and this may have had some influence, because afterward a small piece of charcoal was found stuck to the skin, and on its removal a blister was found under-neath." He had also walked at a quicker pace than Kuda Bux. The last two points are worthy of note, for other instances of each turned up in the course of the subsequent experiments. The first point, with regard to dampness causing hot embers to adhere to the soles, disposes of the "spheroidal state" question, discussed earlier. The second, regarding undue haste, seems to imply possibly that this haste leads to uneven pressure of the feet on the fire. As will be seen, the amateur who finally learned to do fire-walking without self-injury avoided f. antic haste and kept cool. No doubt he discovered an ideal balance between the extremes of haste and its opposite.

Next, Maurice Chapeen tried fire-walking. taking two short, quick steps. His feet were badly blistered and also were bleeding at three points, the latter due possibly to the burnt skin rubbing off the soles of his feet as he hurried out of the trench. His weight was 163 pounds.

Harry Price states that he took a slowmotion picture of the performance and ascertained from it that Kuda Buy had walked much more slowly than the amateurs.

Summing up, Price states that "the poor thermal conductivity of wood ash is not a factor necessary for success: the ash was carefully removed before each walk." And that no one portion of the skin is in contact with the hot embers for as long as half a second. Subsequent observations modified this.

In the more recent of the two London fire-walking reports, named earlier in a footnote, G. Burniston Brown, Ph.D., describes three further fire-walks performed within the past year. Another Moslem magician from India, Alumed Hussain who had walked the fire on many occasions in India, was tested, together with several English volunteers, since Hussain claimed to be able to convey his alleged immunity from burn-

ing to others. The Englishmen of the investigating Council evidently had deep-dyed designs for breaking up the foreign monopoly on fire-walking and planned to build up as early as possible a home industry. They had advertised for volunteers and 40 people volunteered to walk the fire. Those selected, presumably from ordinary walks of life, were Messrs Craigie, Marshall, Bould, Chesney, and Adcock, weighing respectively 143, 145, 124, 177, and 157 pounds. Hussain weighed 126 pounds

Professors C A. Pannett and W D Newcomb tested their fect for possible chemical treatment and washed them in cold water, drying them carefully Hussain had requested a trench 15 inches deep, four feet wide and 12½ feet long This was provided and the fire was laid as before.

The surface temperature of the fire, taken by the physicists with a contact couple, was 575 degrees, centigrade, or 1067 degrees, Fahrenheit, and in the interior it was 700 degrees, centigrade, or 1292 degrees, Fahrenheit, as taken with a standard portable indicator lent by the Cambridge Scientific Instrument Company, Limited

Hussain, after reciting prayers from the Koran, stepped into the fire and took three quick strides in 13 seconds (Frodsham stopwatch reading to one hundredth second) and was not burned.

Hussain had claimed that he could convey his immunity to others, so the experiment shown in one of the illustrations was made. Messrs, Craigie, Marshall, and Bould lined up behind him, holding hands, and the foremost clutching his belt. They crossed the trench in about 15 seconds. (What are the feelings of a novice as he is about to plant his naked foot for the first time on red-hot embers?) "All were burned to a varying, but slight, degree," the Report states, "but only one (to whose foot a piece of ash had adhered) complained of any feeling of pain."

Adook then walked across alone, taking three steps in 14 seconds, followed by Chesney. "They were also slightly burned," the Report states, "and it was found that where the number of steps had been univen, the foot that had been down the more often was the more affected. This indicated that the injurious effect was cumulative."

Hussain then declared that he could walk any distance without being burned. He was therefore asked to walk continuously around the fire but discovered that he must always walk forward in a straight line!

On another day, the trench, now increased to 20 feet long and with the surface temperature of its fire 740 degrees, centigrade (1364 degrees, Fahrenheit), "Hussain, after muttering the usual prayers, crossed the trench in 2 3 seconds, taking six steps, and complained at once of being burned; he was found to have five blisters on one foot and marked crythema (reddening) on the other, a condition closely resembling that of the amateurs after four steps. He refused to walk again, attributing his failure to lack of faith."

Adcock then walked the trench, taking only four steps, and showed slight signs of burning. Later he crossed in dry rope-soled shoes, taking seven steps, and the soles were not burned at all. Bould and Russell next walked the trench and both were slightly burned.

One of the rope-soled shoes was then wetted and held in contact with the fire.

OBLONG ROOTS?

This is an algebraic square $(u-3)^2=(u-3)$ $(u-3)=u^2-6u+$

This is an algebraic square root $\sqrt{u^2-6u+9} = \sqrt[4]{[-(u-3)]^2} = 0$ $\sqrt[4]{[-(u-3)]^2} = (u-3)$ or -(u-3)

This is an algebraic oblong (u-3) $(u-2)=u^2-5u+6$

This is an hypothetical algebraic oblong root, $\sqrt[3]{u^2-5u+6}=\sqrt[3]{(u-3)}$ (u-2)=(u-3) or (u-2)

That hypothetical formula merely illustrates the analogy of the idea 'oblong toot' to the idea square root', the formula does not define a determinate algebraic operation

Squares and square roots are equivalent to algebraic rotations in the plane of complex numbers

The plane of complex numbers floats in the space of bitoliate numbers

Oblong powers and oblong roots, which are indeterminate operations in complex numbers, become determinate operations in bifoliate numbers and are equivalent to polyarithmic (nonalgebraic) rotations in the space of bifoliate numbers

This is a polyarithmic oblong power $(u - 3\&2) ? = (u - 3\&2) - (u - 2\&3) - u^2 - 5u + 6$

This is a polyarithmic oblong root $\sqrt[3]{u^2 - 5u + 6} = \sqrt[3]{(u - 3\&2)/t}$ or $\sqrt[3]{(u - 2\&3)/t}$ (u - 3&2) or (u - 2&3)

This simple application of polyarithmic roots to the formal solution of quadratic algebraic equations may be extended to equations of higher degrees which are incapable of solution by means of the usual algebraic roots. This thesis is developed by Robert A. Philip in three monographs

LABORÁTORY SPECIALTIES, Inc. 132 South Wahneh Street, Wabash, Indiana

Several seconds elapsed before any sign of steam appeared, showing that the spheroidal state—the sudden formation of an insulating layer of vapor-does not occur under the conditions obtaining in the fire-walk.

It was very noticeable that the feet sank into the embers, the Report continues, to a depth of between two and three inches, so that the upper part of the feet were covered. It is very evident that the very low thermal conductivity of smouldering wood prevents damage to normal skin and other objects, if the time of contact is below about half a second and the number of consecutive contacts is not too great.

In a third and final experiment, with a nine-inch, twelve-foot trench, and a stiff breeze which raised the surface temperature of the fire to 800 degrees, centigrade, or 1372 degrees, Fahrenheit, Hussain crossed taking four steps and was uninjured. Then Reginald Adoock walked the trench in 1.8 seconds, taking three steps. He was not burned in any way and he made a statement that, no doubt, has immediate bearing on success in fire-walking, he said that former attempts had given him confidence to walk steadily.

The Report then shows a comparison that is of interest, since it makes clear that in three trials the English novice-an average man such as the present reader is likely to be-had easily equalled the Oriental "professionals" (Kuda Bux had stated that for several consecutive years he daily performed the feat at an annual religious festival which lasted a week). Kuda Bux, Hussain, and Adoock, weighing respectively 120, 126, and 160 pounds, walked distances of 11, 12, and 12 feet, taking 4, 4, and 3 steps, in 22, 16, and 1.8 seconds, in minimum time of contact per step of .55, .40, and 60 seconds, over surface temperatures of 806, 1472, and 1472 degrees, Fahrenheit "It will be seen," the Report points out, "that both Hussain and Adcock exceeded Kuda Bux's performance by walking on a fire of nearly twice the surface temperature. Further it is remarkable that Adcock should have survived, without injury to his feet, the greatest minimum mean time of contact."

What, then, in sum, is the secret of firewalking? Dr. G. Burniston Brown, the author of the Report, sums it up as follows (slightly condensed).

"The fire-walk is in no sense a trick; the walk is performed in the normal manner with bare and chemically unprepared feet.

"Owing to the fact that the surface of the fire is a very unstable one and the feet may sink in several inches, it is impossible to walk so that a constantly changing portion of the foot is in contact with the hot embers this would be possible on a firm plane surface) and skill of this kind is not a factor necessary for success. Nevertheless, steadiness in walking is an advantage in order to avoid remaining with the weight on one foot for too long an interval.

"Moisture on the feet is a disadvantage. "The spheroidal state does not occur.

"No abnormal degree of callosity of the feet is required.

"Fasting or other initial preparation is not necessary.

"No evidence was shown that immunity from burning can be conveyed to other persons.

"The fall in the temperature of the surface of the soles of the feet during the experiment was possibly due to a number of |

steps being taken on the grass after leaving the fire, before the place of examination was reached.

"Immunity is not due to contact with layers of relatively cold ash in which combustion has ceased, since in experiments with Kiida Birx the ash was removed, and, in any case, the feet sink in sufficiently fai to be in contact with the burning embers and small flames below the surface

The equivalence of the performance of one of the amateurs with that of the professional fire-walkers, and the small differ ence between their performance and that of the other amateurs (the professionals could not take more than two steps with cach foot without injury), together with the fact that the immunity could not be transferred, indicates that the slight immunity shown is not sufficiently abnormal to require the hypothesis of a specially induced mental state, for example, 'faith' The fact that no signs of burning were found on the dry rope soled shoes (which can hardly be supposed to be affected by the mental state of the wearer) leads to the view that the secret of the fire-walk lies in the low thermal conductivity of the burning wood. The thermal conductivity of copper, for example, is about 1000 times greater than that of oak wood

'In order that damage may be caused to the skin or other substance by contact with a hody hotter than itself, it is necessary that a certain quantity of heat should enter the colder body, and that the time during which this transfer takes place should not be too long, otherwise the heat may be conducted or radiated away before the temperature has risen sufficiently. Consequently, in spite of a large temperature difference such as exists in the fire-walk, the quantity of heat transferred may remain small if either the thermal conductivity is very low or the time of contact is very short. In the case of the hre-walk, burning wood and its ash are very poor conductors of heat, and, furthermore, the time of contact is not above about half a second in normal quick walking Even so, successive contacts of this period cause an accumulation of heat sufficient to cause injury, and the experiments have shown that with fires whose temperature is 500 degrees, centigrade, or more, only two such contacts can be made with each foot without erythema or blistering.

Dr. Brown, in clearing up lesser details, remarks that "it is to be expected that a people who normally walk with bare feet, especially on the hot ground in tropical countries, will exhibit a greater resistance to injury than the volunteers in the experiments in England, and hence it may occur that, in India for instance, the fire-walker's limited immunity is in no way unusual." He also alludes to the hypothesis of hypnotism and refers to some side experiments that were made at Maudsley Hill Mental Hospital showing that, although subjective feeling of pain may be considerably lessened by hypnotism, any inhibition of normal skin reactions to burning can be only slight. With regard to things of this kind, or to things physiological such as the possible power of inhibiting the activity of the sweat glands of the feet, it may be said simply that these crutches are not necessary, for the facts of a purely physical nature—namely, brief contact, few contacts and a poor conductor of heat-seem sufficient to account for the ability to do fire-walking.

PHOTOGRAPHIC PARTY

FOR those parties with a purpose—aside from the purpose of sheer pleasure-making—such as raising money for a worthy charity or some other noble cause, this department has positive proof that photographic "bait" is well worth consideration

Faced with the problem of devising an attractive method of raising money, at the same time giving the donors something for their contribution that was worth what they paid for it, this department was approached on the subject of how to attain this end by giving the party a photographic flavor.

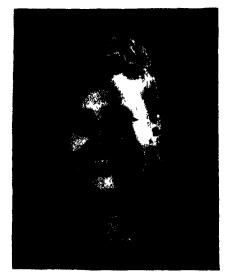

The plan finally approved was to set up a kind of "studio" in one of the rooms of

the house in which the affair was to be held A main light, diffused, was set up at the conventional 45 degrees in relation to the background and a spotlight was employed for an emphasis light. These were made ready before the guests arrived and a camera was set up on a tripod so that picture-making could commence with the least fuss and danger of possible interference. The camera used was a 9- by 12-cm filmpack-plate type, equipped with a telephoto lens of double normal focal length. The background consisted of drawn window curtains which were fuzzed out by the large diaphragm opening—f/55. Subjects sat on a backless bench

The names of the victims were gathered

Party portraits with a purpose. These four are examples of the type of work that can be done rapidly if you follow the suggestions given in the note above

m advance, permitting a steady progression after picture-making began. For the sake of the sitter and to facilitate the making of pictures, the door of the "studio" was closed each time. This helped both the sitter and the photographer, and as a result matters went along very smoothly

While the lighting was, in the main, the same for all, the spotlight as well as the general illuminant had to be shifted occasionally to suit different personalities. Also, of course focusing was arranged for each individual in view of the shallow depth of the long-focus lens, but masmuch as the ground glass had to be inspected for subject composition answay, the frequent focusing was not undily bothersome.

Off-hand, it would seem that the best camera for the purpose would have been a minia ture and the pictures made one after another with little interruption between each one. But in view of the fact that the number of persons involved was not great and the desire of the photographer and the sponsors of the event was to give the best possible performance for the money, the larger camera was chosen and an attempt made to compose each picture carefully. Your money's worth, was the keynote of the interprise.

The price of one dollar for single portraits and one dollar and fifty cents for portraits of couples was found to receive practically universal acceptance. Out of a relatively small group, a total of 20 dollars was collected Enlargements, a sample of which was shown to prospects before picture-making began, were made on 8- by 10-inch double weight stock, semi-matte surface.

In addition to the picture-making, three 11 by 14-inch enlargements of favorite negatives taken from the files were mounted on 16- by 20-inch exhibition mounts and sold by lottery

It is needless to say, of course, that the photographer engaged in such a strenuous venture as this may make up his mind that he will see practically nothing of the party!

LEICA IMPORT

DIFFICULTIES ordinarily encountered with U. S. Customs officials by Leica owners who want to bring their camera back into the United States upon returning from a trip abroad may now be avoided An "Import Certificate" is being issued with each new Leica camera, lens, or Leitz hinocular which has been imported through regular channels. This consists of a small card on which is stamped essential identification information concerning the camera, and assurance that full duty has been paid on the particular camera.

SECRET CAMERA NOTE FROM ASIA

EWS of bustling activity in the manufacture of photographic equipment and materials in China and Japan has come to us by way of a friend of a friend who recently received a letter from Shanghai In part, this letter discloses:

"It way interest you to know that the Japanese are now making the most extensive photographic products imaginable. They include: films for Leica, the 'Canon'; an

amphibious Leica-Contax, called the 'Baika', Leica-type with 'Lausar' / 3.5 lens, 127 film size; and a score of 620 roll-film cameras with Japanese made Compur shutters and lenses. For the first time, a Chinese company is making cameras, box-type, lens ground in Shanghai first batch of 10,000 destined for India"

Making Pactures of the Picture Makers

TRAIN your camera on the camera shooters the next time you go strolling in search of picture material It's lots of fun. The important thing as in all candid shoot

Picturing a picture maker

ing, is to make sure you are not observed by the victim. This is comparatively simple ashe, or she, is probably so engrossed in focusing and viewing his own subject that he or she pays little heed to anything else that may be going on around.

CONTESTS

NEWS of photographic contests comes to us this month from two fronts

Commemorating the 100th anniversary of the birth of photography, the manufacturers of Rolleiflex and Rolleicord cameras are sponsoring the First International Rollei Competition, with prizes totaling 500 cash awards headed by a first prize of \$200 In addition, many of the winners will be represented in a Rollei picture book tentatively titled "The Magic of Light"

"Anything that makes a good picture' is the sponsors' only requirement, with "no restrictions as to subject or quantity of pictures to be entered." Artistic ment and general interest are to be the bases of judgment. Prints must be enlarged to at least 5 by 5 inches, though original color transparencies are acceptable. All entries must be mailed before August 31, 1939 and prizes will be announced December 1, 1939. American entries may be mailed to Burleigh Brooks, Inc., 127 West 42nd Street. New York, New York. Rules and entry blanks may be obtained from the latter or from the local Rollei dealer.

Increased prizes and decreased entry fees are the features of the Second Annual Competition in News and Pictorial Photography at Kent State University, Kent, Ohio, under the auspices of the Department of Journalism. The closing date for submission of entries is March 1, 1939. The prizes this year will consist of a first prize of \$40 and (Please turn to page 184)

WILLO JR. ENLARGING EASEL

The Willo Jr. Enlarging Easel holds paper up to 11 x 14 inches and has a built-in adjustable margin device that is operated by a gentle push or pull. This lever accurately adjusts the upper and left margins to any size between 1/16 and 2 inches, as indicated on the conveniently located scale. There are no loose parts to be lost and no possibility of unequal margins. The sturdy metal masking bands keep the paper flat on the board and prevent curling.

Locks automatically Simple to operate. Nothing to get out of order Will-last for years.

TRAVELING CAMERA EXHIBIT

F you live in or near Philadelphia or IF you live in or near index property of Reading, Pennsylvania; New Haven or Rhode Hartford, Connecticut, Providence, Rhode Island, Boston, Massachusetts, Syracuse, Rochester, or Buffalo, New York, you will soon have an opportunity of attending the Universal Camera Exhibit, which is taking to the road under the auspices of the Leica people Consisting of working set ups of specialized Leica camera accessories, such as the photomicrographic, photomacrographic, copying and reproduction devices, and so on, in addition to the complete line of Leica cameras and more than 500 accessories, the exhibit will be in charge of Anton F Baumann, Leica expert, lecturer, and photographer In addition. Mr Baumann will demonstrate his methods of making giant enlargements and will lecture on color photography

The exhibit will be on display for three days in each city from 1 to 10 PM Exact dates are available from local Leica dealers

IN PRAISE OF THE CHANGING BAG

DECENTLY we had occasion to use a Recently the film changing bag under circumstances which did not easily permit the unloading and reloading of cut-film holders. Since we chiefly employ the miniature type of camera if shooting when away from the studio, the need of a changing bag does not often arise, but when it is needed, it plays its rôle ad mirably. A word of caution to those who are using the changing bag for the first time. Do not attempt to unload the holders and reload them during the same "session." Introduce a box and a protective opaque material such as black paper into the changing bag with the holders to be unloaded. Unload the holders, wrap the film with the opaque sheet of paper and place in the box, after tightly closing the box, end that particular chapter of the session. For reloading, return the empty holders to the bag, accompanied by a new box of cut film and load in com

WHY IS A PRIZE PICTURE?

7 ITH Norris W. Harkness, columnist for The Camera (Philadelphia) and Nature Magazine, we recently collaborated in the judging of photographic prints submitted in a club competition. We could select only two prints in each of three classes, a First Award and a Second Award

Those finally chosen were picked out because they were well or satisfactorily composed, the printing quality was good, the subject matter interesting. Those that fell by the wayside had in several instances sinned chiefly because they lacked but one of these three qualities. If the subject matter of one was good, it lost out because the negative was under- or over-printed; in another the printing was satisfactory but the

So You Want to Take BETTER PICTURES

By A. P. PECK

Associate Editor Scientific American

Camera Owners:

This is THE book you need to get the best results in photography

QUESTIONS that you want answered, things that puzzle you, all are explained in simple, straight-forward style, free from technicalities. Written for those who have their developing and printing done by the photo shops.

LONG experience as an amateur photographer himself, and constant contact with other amateurs who are eager to learn, have enabled the author to anticipate your questions, to put the fundamentals of photography on such a basis that they can easily be absorbed.

THE next best thing to a face-to-face chat with one who has been through the mill and has learned by experience is to have at hand a copy of this book. You will read it first as an enjoyable, running story of what you can do with your camera; you will keep it always at hand for reference and help.

SOME of the phases of photography that are covered: Your Camera and How It Works; Lens Speeds and What They Mean; Exposure; Lighting Indoors and Out; Portraits; Landscapes; Tricks With Your Camera; Action Pictures; Your Pictures Can Be Enlarged; Equipment; and many others.

SCIENTIFIC AMERICAN

24 West 40th Street

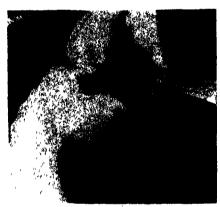

New York, N. Y.

picture content was presented without imagmation. One fault that was particularly noticeable was the evident misunderstanding of the type of picture suitable for submission in a competition of this sort. For example, a dish of fruit that was remarkably well printed had to be discarded because of the commercial type of lighting employed in making the picture: an even light from both sides. Another picture of this type was one showing a bowl of flowers on a table and a woman's hands engaged in arranging them.

A prize picture, therefore, would seem to be that one which possesses all those good qualities which combine to make the print that stands above the crowd. Interesting subject-matter probably comes first, followed by proper selection of viewpoint and good composition, selection of the proper paper contrast for the negative employed and a printing depth sufficient to record the tones of the negative within the capacity of the paper. One careful worker has made it a rule never to enter the dark-room with more than one negative and to work with that negative for all it was worth. Sounds worth while.

THE BELLOWS MAKER

To those in the know, bellows-making is considered one of the most skilful of the arts dealing with the manufacture of photographic equipment. The illustration shows

Bellows making

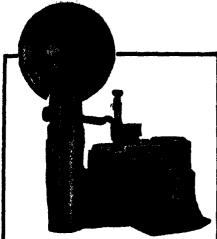

the method by which the bellows are folded in the familiar "accordion" fashion. The hands you see were taught their cunning by a master in the craft as they, in turn, will demonstrate the art to another in the future.

TREATISE ON EXPOSURE

A COMPREHENSIVE and rather extensive treatment on the subject of exposure, exposure meters, and their proper usage, discussion of the meaning and importance of the various film-speed rating systems now in use, plus much other useful information on the subject, is now under way. The guide, as it is intended to be, accompanied by a compilation of the latest film-speed ratings for the various emulaisms now available, is being compiled under the direction of Joseph M. Bing, F.R.P.S.

STRAIGHTENING PRINTS

MANY workers experience difficulty in flattening out prints after they have dried. The knack of straightening prints by

SCIENTIFIC AMERICAN

24 West 40th Street

New York City

the method of passing the backs of the prints over the table edge or under a rule, is not always successfully employed, sometimes resulting in unpleasant cracking. One very effective method is to moisten the backs of the dried prints with cotton, cloth, or a sponge, insert the prints between blotters either in a print press or under a weight, such as a number of books, and leave them overnight. The next morning the prints will be found to be perfectly flat, and will stay

VARIABLE DIFFUSION SCREEN

OUR different diffusion degrees are possible with the home-made diffuser shown in the illustration. The device consists of a pair of knitting or embroidery hoops, four

Diffusion screen

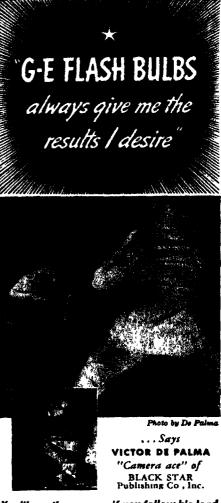

pieces of cheese cloth and a bit of scotch tape to hold the ends of the cloth to one of the hoops. In use, a piece of cloth is inserted in the hoop, while the others hang free out of the way For greater diffusion, more of the cloths are added

SUCCESS WITH THE WIRE FINDER

COME camera users appear to have diffi-Culty in employing the wire or frame finder on their cameras. They complain that the picture they get is different from the one they saw in the finder The fault probably hes in the method of using the finder. This finder is accurate for all practical purposes if the eye is held close to the small opening at the back of the finder and an effort is made to see the outline of the frame and to enclose the view within this outline. Unless these two precautions are observed, the picture will differ from the view

SEE YOURSELF AS THE CAMERA SEES YOU

LACING a large mirror behind the camera to permit the sitter to see him or herself approximately as the cameraman has arranged matters on the ground-glass or in the view finder, has been suggested as a possible aid in making portraits. The contention seems to be that if the sitter can see himself in the mirror, he has a feeling that he is taking a real part in the actual making of the picture and can more easily assume a natural pose and expression. Since the suggestion was made by several persons independently of each other, perhaps there is something to it after all. At least, there is no harm in trying it.

You'll say the same...if you follow his lead

The split-second flash of G-E MAZDA Photoflash lamps makes it easy to get good photos indoors or at night ... natural fullof-action shots...the kind you're proud to show. That's why press photographers use them. Yet they're simple to use. Results are sure . . . if you follow simple directions on package. Grand for color. Each lamp gets one picture. Buy G-E flash bulbs where you buy film.

For dozens of shots with "super" type film ... get G-E Photofloods

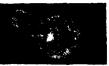

The brighter, whiter light of G-E MAZDA Photoflood lamps lasts for dozens of pictures. Two No. 2 G-E Photofloods and new "super" type high speed film permit snapshots at night or indoors...even with a or indoors...even with a box camera. And they're swell for home movies!

For best results, be sure to get G-E

WHAT'S NEW

In Photographic Equipment

Alf you are interested in any of the items described below, and cannot find them in our advertising columns or at your photographic dealer, we shall be-glad to tell you where you can get them Please accompany your request by a stamped envelope

Universal Safelight Outfit (\$1.95) With interchangeable safelight filters. Complete set includes black enameled safelight

lamp; A-3 green safelight filter, A-7 red safelight filter; and 10-watt yellow bulb. Used in lamp without filter, yellow bulb provides safelight illumi-

nation for contact printing papers. With red filter may be used for orthochromatic films, with panchromatic, except those requiring development in total darkness, yellow bulb and green filter are used Lamp fits any standard electric outlet

ZENOPRINT KIT (\$100) Contains materials for making contact prints without use of dark-room. Process utilizes newly introduced Safelyte Paper, with orange repellent dve Dve disappears in fixing bath, leaving ordinary black and white print. Kit includes, besides paper, special developer containing red light-repellent dye, standard hypo solution and special flexible printing frame. In operation negative and paper are placed in frame, latter bent for perfect contact, in front of ordinary electric light bulb and exposure of several seconds is given, followed by development and fixing in the usual way Additional supplies of paper may be purchased separately, sizes ranging from 2% by 41/2 inches to 5 by 7 inches

IMPERIAL PRECISION FASCI (\$9.95) Allmetal, plan-parallel paper surface, sil ver-blast focusing surface Margin masks, with controls at both ends, and adjustable white horder control for squaring up paper with easel and masking bands and giving measured white border to prints. Makes up to full 11 by 14-inch prints

LOCK-SHARP (\$3.00) Light-tight self-closing box for protection of photographic paper while working in dark-room. Automat-

really locks out all light, giving positive paper protection when cover is released Cover drops into C light trap which prevents possibility of fogging pa-

per Strips supplied with box permit separating different contrasts or types of paper Type now available for 8 by 10 paper can be used for smaller sizes. Larger sizes will follow later.

Utilo Filters, Combination Lens Shades (filters \$1.35 to \$2.50 each, shades \$1.20 to \$2.00 each). Filters, available in three yellow densities, orange, red, green, and blue, furnished in sizes 22 mm to 42 mm. Metal-mounted, slip-on type filters of solid glass dyed in the mass Featherweight metal mounts fitted with three adjustable prongs to provide firm and uniform grip on lens.

BOOKS

BOOKS

Amateur Photographers

WAYS IN PHOTOGRAPHY, by Jacob Deschin. Eminently practical from every point of view, this new book contains nothing of theory and nothing that the advanced amateur photographer will not find valuable in one way or another. It covers the whole range of amateur photography, discussing such things as trick pho-tography, photomurals, retouching, infra-red, and a number of other sub-divisions that will not be found elsewhere in as clear and concise a manner. \$2.90.

INFRA-RED PHOTOGRAPHY, by S. O. Rawlings. A treatise on the use of photographic plates and films sensitive to infra-red. Exposure and processing are fully covered; formulas are given for sensitizing, \$1.65.

Universal Photo Almanac and Mar-KET GUIDE. How, when and what to photograph in order to make money with your camera; where to sell different types of prints \$100

CAMERA LENSES, by Arthur W. Lockett. Explains simply and clearly, yet with scientific accuracy, all the underlying principles of lenses. \$1.10.

CHAMPLIN ON FINE GRAIN, by Harry (hamplin, A complete hand-book on the entire subject of fine grain, in-cluding formulas and how to compound and use them. \$1.90.

PHOTOGRAPHIC HINTS AND GADGETS, by Fraprie and Jordan. How to make all kinds of photographic accessories; from film clips to cameras to lighting equipment, and so on; 250 articles and nearly 500 illustrations. \$3.70.

ELEMENTARY PHOTOGRAPHY, by Neb-lette, Brehm, and Priest. You can learn much of the fundamentals of photography from this little book even though you have little or no knowledge of physics and chemistry.

PHOTOGRAPHIC ENLARGING, by Frank-lin I. Jordan, F. R P. S. One of the most interesting and authentic books on enlarging. Its 224 pages cover every phase of the subject and 75 illustrations, many of them salon-winners, show the value of correct technique. \$3.70.

PORTRAIT PHOTOGRAPHY, by H. Williams. Fundamental principles of composition and lighting, paving the way to satisfactory results in this particular branch of photography. \$4 45.

LEUDI

Helps You Get the Picture

Is feather-light, quick, accurate and has wide light range Ideal for every camera fan, for any camera or film, un-der all light conditions You should not be without it.

Complete with case only \$2.15

Write for Literature Mimosa American Corporation 485-5th Ave. New York Each filter supplied with leather purse case without extra charge. Combination lens shade furnished in sizes 24 mm to 42 mm. Made of lightweight, strong metal finished in dull, anti-reflection black. Metal ring built inside Utilo shade to take Utilo filter of same diameter. Leather case available for shade at 50 cents extra.

PERCIA ULTRA TINE GRAIN DEVELOPER May be used below or above its optimum temperature without noticeable ill effect on negative. In addition to grainless silver image, a stain image is produced

COMBINATION TABLE TRIPOD AND TILT TOP (Complete, \$200, tripod or tilt top separately, \$1.00). Measures 71/2 inches, solidly built Has three removable legs furnished with rubber tips. Tilt top of solid brass with swivel ball socket permitting forward or backward tilt of 180 degrees and swing in any direction.

Perduro Hardener for use in any ordinary developer. Has mild tanning action and increases resistance of emulsion to mechanical damage and differences in temperature between processing baths.

Mendelson's Speedcuns: Both Universal model and Model C (for Speed Graphic) now feature adjustable aplanatic reflector for accommodating differences in bulb sizes. New hulb socket, with improved method of making contact. All wires removed from battery case

New model for 21/4 by 31/4 Speed Graphic Provides leads and connectors for focalplane shutter synchronization in addition to standard front shutter synchronization. Normal operating condition with two cells in battery case, for using more than one bulb, or in other cases affecting greater drain on the circuit, extension tube is provided With this tube, case holds three cells

PERUTZ PERGRANO "Only single layer panchiomatic film in America" Inherently fine grain, is claim, obviates use of ultra fine grain development. Very short developing and fixing time claimed for it due to single layer of emulsion

LABORANT 5 by 7 ENLARGER (\$289 00): For negatives up to 5 by 7 inches (13 by 18 cm) Has double condenser; counterbalanced head, tripod suspension post for vibrationless manipulation, friction drive for micromatic focusing; horizontal projection; large lamphouse, and other features Double extension bellows permitting reducing as well as enlarging. Complete with Betar 1/1.5, 21 cm lens

MAZDA PHOTOFLASH LAMP No. 21 (20 cents) Same size as standard 60 watt Mazda lamp; smaller than present No. 20 Mazda Photoflash lamp, yet gives more light. Lumen second output 50,000 to 60,000, compared with 45,000 lumen second rating of No. 20. Light spread over longer time. Peak of flash accurately timed. Lamps filled with foil which allow flashing by contact. "Quick break" filament burns out almost instantaneously after igniting flash material, thus reducing drain on dry-cell power. Manufacturers claim "satisfactory pictures can be

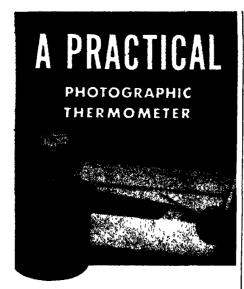

Clty.

Si-Mi X-Y Reversal Compound enables you to process your Dufaycolor Film without removing the film from your tank. Completely eliminates light flashing and re-development. Process your own color film with SI-MI X-Y REVERSAL COMPOUND which in conjunction with the Dufaycolor Developing Kit completely develops Dufaycolor or any black and white reversal film in 15 minutes. UNIVERSAL PHOTO ALMANAC AND MARKET GUIDE 1939

MATEUR photographers who AMATEUR protographics feel that they should be able to make money with their cameras will find in this book many hints that will be of value. A series of articles tells what, when, and how to photograph, how to sell vour photographs profitably, how to handle your equipment, what picture journalism consists of and how to make contacts with editors, and many other things that the would-be photo journalist will want to know. A pictorial section presents some of the work of this country's foremost photographers; a large formulary gives in compact form most of the standard formulas. The market guide section tells who purchases what kind of photographs, approximately the price paid, and gives other pertinent data regarding hundreds of publications that are in the market for photographs.

Q. What are the advantages and disadvantages of hypersensitizing film in order to increase its speed?---J. C.

4. The fact made public by Agfa Ansco Research Laboratories that film emulsion subjected to the action of mercury vapor can be increased in sensitivity from 50 to as high as 150 percent of the original speed, is obviously a boon where great film sensitivity is required. This is the great advantage of the process. Another is the fact that if a roll of film is known to have been underexposed, the hypersensitizing treatment can be applied after exposure to "add" the required speed up to as much as 100 percent or double the speed of the film when exposed. Also, the maximum effect of the process is obtained by treatment both before and after exposure of the film, bringing additional speed up to 150 percent. The disadvantages, if so they may be called, include the length of the hypersensitizing period, 30 hours for loosely rolled, uncovered film, and from 6 to 8 days for paper backed spools or 35-mm magazines, and that if there is too great a lapse of time (three to four weeks) between the completion of hypersensitization and actual exposure of the film, the added speed wears off

Q. Our high school is planning to purchase a camera suitable for taking all pictures needed in their year book. We take most of the pictures indoors. The camera should be one that will take both group pictures and portraits. I. should appreciate it if you would give the approximate cost of such a camera and the names and addresses of dealers handling these cameras.-R. F.

A. A proper reply to your inquiry can be made only with a knowledge of several factors not included in your inquiry; namely, the amount of money you are willing to spend on this equipment, the size negative you desire and whether you wish to print by contact from relatively large negatives or to make enlargements from smaller negatives. In the latter case, of course, you will require an enlarger unless you intend to have the processing done by a photo finisher. Quite a number of camera types are suited to the sort of work you have in mind, from the 35-mm miniature up to the professional 8 by 10. Generally speaking, for group and

single portraits, a view camera affording negatives 4 by 5 or 5 by 7 inches, or a filmpack camera exposing negatives 31/4 by 41/4 or 4 by 5 inches, either camera equipped with a lens of at least 1/45 maximum aperture, should be most suitable and least expensive for the kind of work you indicate We are assuming that the negatives are to be printed by contact. We refer you to the advertising columns of this magazine for dealers who handle various types of camera-

Q. When using glossy bromide paper, I find it has a bad curling tendency which makes it difficult, after exposure, to immerse it properly in the developing solution; that is, to insure the developer covering the paper evenly to the edges from the start. Can you suggest how the paper may be straightened to avoid this inconvenience?-D. C. K.

A. One of the surest ways, of course, 18 to make up a generous volume of developer solution (which is rather wasteful), so that even if the edges of the paper do curl considerably they will be submerged by the depth of the bath, aided by quick manual immersion. The problem is to flatten out the paper before the developer has a chance to do its work. What's wrong with immersing the exposed paper in a tray of plain water and when the paper has become watersouked and, as a consequence, straightened out, shpping it into the developer? Make sure, of course, to drain the excess water from the paper as thoroughly as possible, before immersion in the developer, to prevent undue dilution of the latter.

Q. In copying articles from journals I have used contact paper to make a negative from which I make a copy of the article which I want to keep. In making my negative I place a piece of sensitive paper (Velox No. 5 single weight) sensitive side toward the printed matter and have the light pass through the sensitive paper; thus the black of the printed matter absorbs the light and the paper remains light on being developed. Where there is no printed matter the light is reflected and the sensitive paper becomes black when developed. Is single weight the thinnest

paper available, as the paper I now use is bulky to go into files? Is there a sensitive paper made which will fold without cracking, which I can use for this purpose?—W. A. R.

A. Papers of the folding-without-cracking, thinner-than-single-weight type are Eastman's Solar Bromide or Line Solar Bromide (for contact printing), with dead matte surface; and Agfa's Nokoline and Defender's Document, both the latter in semi-matte surface. We notice that the sample print which you sent with your letter is on glossy, single weight paper, ferrotyped Unless you have a special reason for using a glossy paper, you will find the matte and semimatte papers more suitable and possibly easier to read Besides, these are the only surfaces in which the paper you prescribe is available. We observe in your print, also, numerous out-of-focus areas which were probably caused by improper contact between the magazine page and the "negative" paper We would suggest the use of glass to hold paper and subject in contact and weights or pressure of some sort on all four sides, in addition to a flat surface on which to test the magazine. Since you appear to be doing copying by this method right along, we believe you would find it advantageous to construct a printing frame of the conventional type but with an opening at the side for the pages on the other half of the bind ing as well as the bulky and interfering

Q. Enclosed are three photographs taken with a photoflash bulb at 1/11, bulb exposure, and all taken within a few minutes apart. You will note that in one print the candles are correctly registered and on the other two there appear streaks as though the candles were blazing away but the effect does not register as coming from the candles; in fact it looks as though there were more than the actual number of four. The candles were just lighted and were burning very low. The suggestion that the camera was moved during exposure does not seem to fit the occasion as the other objects are all sharp. Can you offer any explanation?-F. K.

A. From the streaky appearance of the flames and the fact that the flames seem to be "disengaged" from the candles themselves, our guess is that you held the camera in the hand, using an ordinary hand flash. The shutter being open for some time before you actually set off the flash, the candle flames were registered on the film and since you moved the camera, this registration appears as a streak. The other objects, as you say, are all sharp because the only illumination they had was that of the flash.

Q. Can you suggest a suitable material other than galvanized iron with which to line a dark-room sink?——P. R. F.

A. Several workers we know have had aminently good success with sheet lead for this purpose. This material being practically mert to acids, other than turning black where the acid is spilled upon it accidentally, no protective coating is required as in the case of such metals as galvanized iron. Lead lining is easily worked because it is relatively soft. However, because of the hazard of cutting holes in it by accidental

dropping of sharp or hard objects, some consider the material to be unsuitable for the purpose. On the other hand, since most sinks of the dark-room type are usually provided with wooden racks upon which trays are rested, the danger mentioned is largely minimized. A suitable thickness for dark-room sink lining is 1/32nd of an inch.

Q. I am quasidering the purchase of an enlarger for my camera and would appreciate it if you could give me some information as to where, what, and the prices of some enlargers. My camera takes a 2½ by 4½ negative, and I would like to have an enlarger to take this and smaller, if possible.—R. J. C.

A. We do not know of any enlarger specifically designed to take the negative size accommodated by your camera. In selecting an enlarger, therefore, it will be necessary for you to make a compromise and to pur chase an enlarger taking negatives up to the longest dimension of the negative made by your camera, which would mean a short dimension of 314 inches. In that case, of course, you will need a special mask for your negatives Since 21/2 by 41/4 inches is a rather odd size these days, you may find that in enlarging you habitually crop a portion of the long side anyway. If that is the case, perhaps an enlarger of the 21/4 by 31/4 or 212 by 31/2 inch size might do. This is not an unreasonable assumption, by the way, witness the numerous instances in which the popular 21/4 by 21/4-inch negatives are cnlarged, not square, but to a vertical or horizontal rectangle. Any of the photographic supply houses whose advertisements appear in our columns will be glad to furnish literature and prices on request.

Q. In ordering from a glass company a large sheet of photographic ground glass for a special purpose I have in mind, how shall I specify my requirements?—L. A. S.

A Ground glass is prepared in several grades of fineness; the finer it is, the more expensive. For best results, when used for photographic purposes, it is necessary to specify "mudground" glass. This is the most expensive and is not kept in stock but must be prepared on special order, except in the ordinary sizes used in conventional cameras. However, it is well worth the extra cost.

Q. In taking pictures of small animals and birds by remote control or otherwise on the sly, I find that the subject is frightened away after the first shot. It seems that the noise caused by the reflex mirror flying up against the ground glass is a little too much for them. Is there any way I can muffle this noise?—C. S. K.

A. You probably know that an eveready leather case, with its felt lining, is fairly effective in softening the noise to a moderate extent. But if you do considerable work along these lines, we would suggest a device something on the following order: Construct a box just big enough to take your camera, and line the box well with some noise-absorbing material. Provide openings for the lens and the cable release, making your focusing arrangements in advance. Of course, the design should also include some such arrangement as hinged doors to provide for inserting and removing the camera.

Half THE PRIZES WENT TO ROLLE! CAMERA OWNERS!

As you may have noticed on pages 182 and 183, just half of the six cash prizes in Scientific American's Third Annual Contest were awarded to Rollei pictures Considering the fact that scores of different cameras were used by the contestants, these figures are very significant Let's analyze the awards

1st Prize in Group I (Portraits) was given to a picture made with a Rolleicord.

2nd Prize in Group II (Landscapes) was awarded to a picture made with a Rolleiflex camera

2nd Prize in Group III (Natural History) was made with a Rolleicord.

Of the 15 pictures awarded Honorable Mention four were made with Rolleicords—and two with the Dolling (another camera distributed by Burleigh Brooks, Inc.)

WHY SO MANY PRIZE-WINNING PICTURES ARE MADE WITH ROLLEI CAMERAS

Roller is the original twin-lens reflex camerastill the only one that has a separate and faster focusing lens which renders a brilliant image on the ground glass regardless of the diaphragin opening being used on the taking lens, and even under poor lighting conditions

With a Rollei camera you actually see each picture before you make it. And you get 12 negatives in the practical 2½" x 2½" (6 x 6 cm.) size on a roll of standard, economical 120 film.

Roller cameras are now widely imitated. But none of the imitations even approaches Roller cameras in quality or performance. Ask your dealer to show you these latest Rollerflex and Rollercord cameras!

The New Automatic Rolleiflex is streamlined No protruding gadgets Everything is

A Monthly Department for the Amateur Telescope Maker Conducted by ALBERT G. INGALLS

CONTRARY to the kind of opinion that might be offered by the average person having no background about telescopes, if you wanted to design the one single telescope that would make visible at one single view the greatest number of stars, you would not employ high magnification but low

Taking several governing data as the basis of the design, it is possible to figure out the exact characteristics of such a telescope, and this is just what one of the authors of "Amateur Telescope Making Advanced, the companion volume to the lieginner's book "Amateur Telescope Making," has done in that book. This refescope is named the "RFT," or "Richest Field Telescope."

The beginner usually tends to crave high magnification and, when the RFT with its low mag infication was first described some amateurs hesitated to make it, knowing perhaps that their neighbors and friends would rate them low when they heard the answer to the inevitable question, "How much does it magnify?" However, the RFT, magnifying 15 or so diameters, becomes popular and is used usually as an adjunct to the regular" Newtonian magnifying 50 Newtonian magnifying 50 to 100 diameters its comple ment in fact

S. L. Walkden, of London, has described here in previous numbers several modifications of the RFT, and now comes his Herschchan RFT. The Herschehan type of telescope has had a bad reputation, perhaps it can partly reform. Walkden writes.

"Regarding RFT's These instruments need not be of only the refractor and Newtonian types, there is another class of instrument, the Herschelian reflector, which very much claims attention. It does so chiefly on account of its brilliancy, due to the absence of losses of light by flat obstruction and by flat reflection. In the small sizes it is nearly as brilliant as a refractor, and in large sizes more brilliant. Because it needs only a mirfor and evenience its construction is easy and is further made casy, compared with the Newtonian, because the mirrors of long focus have only shallow spherical curves to he ground, and need not be parabolized like the deep, short focus mirrors and mirrors made for high magnifications. Of course, the notable weakness of the Herschehan has always been its defective definition, due to the oblique view and the use of ordinary astronomical magnifying powers, but that can be minimized by giving the mirror a proper focal length. Then, with the very lowest possible powers (which are precisely those of the RFT's, only 35 per inch of aperture). the defect in definition-an occasional trace of cocked-hat shape in the star imagesmust, in many opinions, be considered sufficiently unobtrusive

"In Figure 1, a graph of focal lengths for different apertures, a curve marked GDH (standing for "good definition Herschelian") tells the focal length considered necessary for good definition, because it makes the oblique angle, like α , or EJX in the corner squat diagram of Figure 2, not more than

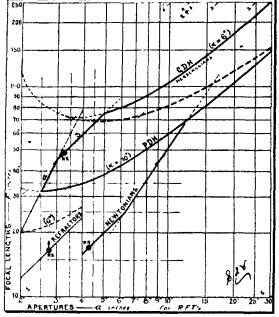

Figure 1: Design data

about 6° This angle has been judged in tests to be the best criterion of definition. [The squat diagram is not to scale

Fd] The formula used for the curve in Figure 1 is F= $(7.5a^2 + 15a) / (a - 1.5)$, but the curve, read to within a few inches, serves as well as the formula If with this focal length the instrument is thought too long to manage, less focal length can be used-with less, however, to be expected in the way of definition; but less length than the PDH (poorer-definition Herschelian) curve of the same figure is not recommended. The formula for that curve is F= $(4.5a^{3} + 9a)/(a - 0.9)$, allowing the oblique angle α to be as great as about 10°.

"From 5" down to 3" aperture, the upper limit of focal length is at the thick straight line marked 3, unless an eyepiece wider than about 3" is not minded. From 3" down to 2½" aperture the upper limit of focal length is at the thick straight line marked a—unless an eyepiece wider than the aperture is not minded! Actually, at less than 4" aperture, and certainly at less than 3" aperture, the refractor, for

which focal lengths are also indicated, is the preferable type of RFT. For it, F=6a is assumed, but $F=5a^2/(a-1)$, shown in the 6° dotted curve, may help the realization of finer definition in these small instruments. Newtonians of greater than 4° aperture are rivals both for shortness and definition, but fade out in both these advantages at over 10° to 15° aperture, and of course are harder to construct

"When the F inches of focal length of the Herschelian of a inches aperture is settled, the focal ratio $c=\Gamma$ a and the width EK across the top of the instrument (see the squat diagram) may be calculated as $0.3\epsilon + a + 3$ inches. The top diameter of the main tube at the focal distance, or diameter DK, is then $a+\epsilon/5$ inches, and the diameter of the focal image, EL, is c 5 inches. The mirror has to be tilted toward the little cross, midway between the points A and B, which points are at the centers of the main tube and the eyepicce tube. The distance AD, which will be found 3" after using the above rules, allows room for the side of the observer's head, as he observes with his back to the sky and with the starlight coming into the main tube over his shoulder

"The three black dots of Figure 1 are for general purpose RF1's of the different types of telescope

"The eyepiece is to be calculated by the simple rules already given in 'ATMA' for the other RFT's of the same aperture and

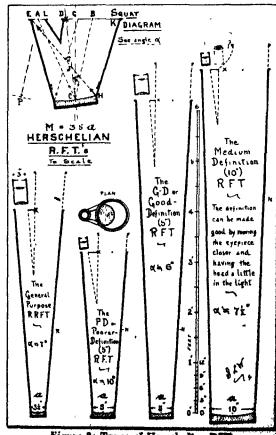

Figure 2: Types of Herschelian RFT

focal length. The little diagonal lines at the very top of Figure 1 indicate some eyepiece sizes, the abbreviation 'e.p.s.' meaning, as will be quite obvious, eyepiece size. For similarly good definition all over the field the eyepiece really needs directing at a point about half way from C to P (squat diagram) but its best direction is easily found on test.

"It is a good plan to give a Herschelian, especially a large one, a focal length according to the heavy dashed curve for medium definition (drawn freehand in Figure 1, not calculated, but formula is $F=(5a^2+15a)/$ (a-2) inches); as, for example, like the 10" instrument illustrated in Figure 2; and then, if the definition is not quite all that is wanted, move the eyepiece closer, so that the head intercepts a little light. The better definition may be considered ample compensation for the little loss of light not exceeding, perhaps, 10 percent. In larger and larger instruments, more and more of the observer may in this way intrude into the main tube till, at some aperture, perhaps about 100", the observer may entirely enter the tube. After that he may go to the center, to observe from there, just as already planned for the 200", and then have no obliquity of view to cause loss of definition.

"The two 5" RFT's illustrated in Figure 2 show how small instruments of identical aperture compare in length and size of eyepiece, one telescope made according to the GDH curve and the other according to the PDH curve. The 31/4" represents the important little general-purpose Herschelian RRFT-superior, at least in illumination, to the Newtonian general-purpose RRFT. It is not according to the GDH curve, but it cannot be made longer without becoming unwieldy and requiring a dreadfully large eyepiece A small number may prefer this Herschelian to a refractor of half its length, on account of the comfortable downward wew, and some may like to bring the eyepiece closer to the main tube, even though the head does then intercept a little light. One idea for keeping the head out of the light when the eyepiece is thus put closer, is to incorporate with the eyepiece a compound achromatic prism, bending the light outward through about a dozen degrees and itself absorbing very little light. Some such prism can be balsamed to the eyepiece lens. A more drastic plan is to use a total-reflection rightangled prism or a diagonal, but that may have more drawbacks; besides, it half turns the instrument back into a Newtonian, although one superior in illumination. There is much scope here for experimentalists to find the arrangements they prefer.

"Shorter Herschelians of good definition may possibly be made by those who specially figure the mirrors, but since parabolization has apparently to be done eccentrically, with reference to an axis nearer AP than to XC (in the squat diagram), only the heroic few, like the makers of Schmidt cameras, may ever attempt that figuring—or perhaps devise ingenious correcting plates.

So long as the insides of the instruments are of the shapes indicated, allowing free passage for the light, the outside shapes may of course be different, according to fancy or convenience. In the limit nothing is absolutely necessary, except a beam or structure rigidly holding the mirror and the eyepiece in their proper relationship, but it seems better to have something like a tube.

"This is written with the awareness that there are some who can never be indulgent

SCIENTIFIC AMERICAN says:

"Every amateur astronomer and telescope maker, and everyone who takes an interest in astronomy should own a copy . No similar book has ever been written"

-Men,-**Mirrors** and Stars

BY G FDWARD PENDRAY

New, revised edition

THF complete popular book about telescopes, the men who make them, and astronomy. This edition contains descriptions of all Ameri contains descriptions of all American observatories and the most detailed account of the 200 inch telescope anywhere available. Lists of telescopes and data about observatorics have been enlarged and brought right up to 1939 with the aid of astionomers and observatory directors throughout the world Pro fusely illustrated, \$5.00

At all bookstores, or by mail from **FUNK & WAGNALLS COMPANY** Dept 1928, 354 Fourth Ave., New York, N. Y.

THE BEGINNER'S CORNER

ALTHOUGH "ATM" emphasizes the desirability of mountings that are rugged and heavy-what the machine designer calls "brutal"-a percentage of beginners build telescopes that are far too lightly mounted. Without wishing in any way to reflect on those who built the first three telescopes shown below—for they by now have doubtless sensed the fault if fault it be -these photographs are reproduced in a group in order to re-emphasize this point. In every case, it will be noted, the telescope itself is excellent, and it is only the mounting, or parts of it, which seem light. In each instance the tubing employed might to good

WAS A SUCCESS.

sions of the axes

TELESCOPTICS

(Continued from preceding page)

toward the definition of a telescope, and who would want to boil in oil one who persuaded them to make a Herschelian, but many more will consider they have found the very thing for brilliantly joy-riding with low powers around the glorious celestial scenery of the Milky Way The first kind are recommended to solace themselves by converting their instruments to high power Newtonians, for the more sober Joya of planetary and double star observation, for which purpose the long focus mirrors are very suitable

IN advance of publication of the above has come a testimonial on the Herschelian RFT, part of a letter from Clyde W. Tombaugh of Lowell Observatory-the amateur telescope maker who discovered the first tangible evidence of the planet Pluto He writes

"Some time ago, Mr Walkden suggested to me that I try out my f/15 long-focus 5" reflector [the one shown in 'ATMA' at page 639 Ed l in Herschelian form as an RFT So I remounted the mirror on a wooden beam, offsetting the incident pencil 21/2" from the principal axis on one side and the center of the eyepiece 214" on the opposite side, and used an eyepiece of $3\frac{1}{2}$ " $e\hat{f}\hat{l}$ and 13," field lens diameter. This gives 33Xstill too high. Nevertheless, the star clouds and dark holes in Cygnus, Sagittarius, and so on were very beautiful. The definition is good over the whole field, 75' of arc in diameter. The off-axis effect is only slightly noticeable on the far side of the field."

Tombaugh adds that his eyepiece was a 45-cent, mail-order catalog 3X hand magnifier $1\frac{1}{4}$ " in net aperture, plus a simple lens of 2" fl taken from another eyepiece, the two separated 2 43" as a compromise on field and power This gave an e.f.l. of 2.3". As no out-size eyepieces, like some of those shown by Walkden, ere known to be purchasable.

the another may have to design his own, in the meantime possibly experimenting with some simple makeshift like Tombaugh's For a 3" (focal length) eyepiece, Walkden offers the following specifications fI, of each lens, 4". Distance of lenses apart, 2.67" Diameter of field lens, 231", of eye lens,

IN a private communication bearing on the Herschelian RFT, Walkden remarks that "perhaps some of the detail improvers will now get to work on special figurings of the RFT, eccentric and the like, to equip it for high-power magnification and a little less length" Well, that is just what two American amateurs have been doing already making an offside paraboloid. But we'll tell about this in a later number

THE telescope snown in 11800.

4" / 5 RFT, ordinary Newtonian type, made by R. B. Rice, 17 Maple St., Saugus, Mass, who save "the results with this telescope are very fine" But when it comes to enthusing over the RFT, as many have, George E. Dunn, 6906 Bingham Ave, Dearborn, Mich, whose 8" f/15 RFT is shown at the left in Figure 4, says. "Mine was disappointing at first and continued to be so until perfect optical line-up was attained. Everest's 'diagonalology' published in your September 1938 number, brings out this matter but it cannot be stressed too strongly for these short focus telescopes. I found it necessary to redesign the diagonal holder to get closer adjustment and more rigid construction before calling it a job. Even then it was not particularly impressive until one night when it was chucked into the rear of the car and taken into the country. That was my first view of the heavens away from the city haze. My vocabulary does not include much in the way of poetic expression, but no one can describe those clouds in Cygnus as seen through an RFT. This goes also for the double cluster near Perseus and count-

Figure 3: Rice and his RFT

less other regions. Diffraction effects are bad when first or second magnitude stars are viewed, and the RFT is useless on planets. On the other hand it out-performs anything I have looked through for terrestrial work."

NO sooner does the telescope owner begin studying the Moon's map than lus curiosity is aroused by the odd names given its formations, mostly names of persons "Who's Who in the Moon" is a newly published, 130-page memoir of the British Astronomical Association in which these names are explained-some 600 of them-and their owners' personal histories told

TH'S COMPLETE SIMPLE PRACTICAL COURSE FOR SELF-INSTRUCTION WILL QUICKLY CIVE YOU

A Complete Mastery of **MATHEMATICS**

Prepare now to advance yourself to an important job by Mathematics I raining Mathematics is the foundation of all mechanical and scientific work, and of all business or industry based on science Without this essential knowledge even the most capable man is left behind while others forge ahead to better jobs, bigger contracts, more money You need mathematics to solve technical problems and to improve, speed up and check on your and the work of others

Now you can karn mathematics by an easy, mexpensive and time - saving method A very simple and extremely interesting course in book form

you by an expert who has devoted a lifetime to teaching practical men the fundamentals of this important subject

MATHEMATICS FOR SELF-STUDY

By J. F. Thompson, B.S., A.M., Dept. of Mathematics, Pratt Institute

These books start right from the beginning with a review of arithmetic that gives voit all special shortcuts and trick methods that save countiess hours of your time. Then they ke right into higher mathematics and show you how simple it is when an expert explains it for you. In no time at all you will be tacking with case the most difficult questions on this subject.

A Complete Course and Reference Library in 5 Volumes

Arithmetic Algebra Geometry Trigonometry Calculus 1598 Pages Illustrated

An Expert's Simplified Methods

Mr Thompson the author of these books has hid many years' experience in mathematical training. He presents each practical method and problem in the clearest, simplest way. He gets right down to the kind of information, that you need in your duly work.

CURRENT BUILD HIS BRIFTS

(The Editor will appreciate it if you will mention Scientific Amer-ican when writing for any of the publications listed below)

A MIRACLE BEGINS, by Dr. W. R. G. Baker, is an eight-page pamphlet that gives the straight facts about television-unsolved problems, programs, consumer problems, size of pictures, cost, and future prospects. General Electric Company, 570 Lexington Avenue, New York, New York, -- Gratis

VOIGHTLANDER EXPOSERS CALCULATOR 18 8 pocket-size chart of the "slide-rule" type which is adaptable to all parts of the world, all light conditions, and all film-speed ratings Willoughbys, 110 West 32nd Street, New York, New York -15 cents

PROTECTING PURITY CONCIDENCE IN PERIOD. ICAL ADVERTISING IS a 16 page booklet that tells of the work which is being done to insure that the advertising columns of periodicals be kept free from objectionable copy. It is of particular interest to executives and department heads in all concerns which use any form of periodical advertising National Better Business Bureau, Inc., 405 Lexington Avenue, New York, New York ---Gratis, as long as supply lasts

INDUSTRIAL PRICE POLICIES IS a 32-page booklet based upon a research study made by the Brookings Institution, answering such questions as "What would lower prices mean to business?—to profits? How are prices set in our modern industrial system? How can they be reduced without loss to stockholders or workers? What can the industrial executive do about prices?" Public Affairs Pamphlet No 23 Public Affairs Committee, Inc., 8 West 40th Street, New York, New York -10 cents

HATCH-O DATE is a chart designed to be used by poultry raisers and is especially helpful when several hatches of eggs are placed in the incubator at different times The chart is designed for eggs having 21 day incubation, but a correction table is furnished for other eggs. The chart includes a monthly calendar. Pope Brooks Foundation, Inc , Aton, Conn -10 cents.

LIGHTNIN PORTABLE MIXIRS is a lavishly illustrated eight-page pamphlet that shows various types of gear-driven and direct drive mixers for use in many process industries where small or large scale mixing of batches is a regular part of the procedure. The mixers described are adaptable to use in all types of tanks and cookers. Mixing Equipment Company, Inc., Rochester, New York -- Gratis

Viscosity Tubes is an eight-page pamphlet which describes the air bubble method for determining the viscosity or body of varnishes and lacquers, as well as the equipment necessary for this test. Also listed are a number of other devices of interest to

chemists in general as well as to paint and varnish workers. R. P. Cargille. 118 Liberty Street, New York, New York .- Gratis.

Tego-Bonded Construction is a 32-page illustrated booklet which describes a modern method of producing plywood and related materials. This type of construction offers the user a panel that is durable, economical, and of practical utility. The method is based on a hot-bonding process wherein the component layers are permanently fused together with dry sheets of a synthetic resin The manufacture of the panels is described, as are also many of the uses which it finds in diversified fields. The Resinous Products & Chemical Co., Inc., 222 West Washington Square, Philadelphia, Pennsylvania. - Gratis

THE RAH WAY HANDBOOK, 1938-1939, is a paper-covered book which is designed to provide students and other interested parties with a collection of useful statistics and information, particularly regarding the railroads of Great Britain and Ireland A number of the tables give international comparisons. In the statement regarding the electrification of steam railways it was deemed necessary to cover the whole world in order to present a complete picture of this increasingly important development Of wide general interest is a ten-page chronology of railroad history. The Railway Magazine, 33 Tothill Street, Westminster, London, S W. 1, England 2 shillings and Stypence

HANDLE THE LLICA IS a small booklet that is essentially a straightforward sales talk for one particular type of miniature camera, but it contains considerable information which will be of value to any amateur photographer. Request Pamphlet No. 7784 E Leitz, Inc., 730 Fifth Avenue, New York, New York -Gratis

THE TIME LAG IN GAS-FILLED PHOTO-HICTRIC CITIS, by A.M. Skellett, is a 10page pamphlet, illustrated, which describes time lag measurements as made with a light chopper on a gas-filled cell of special design Bell Telephone Laboratories, 463 West Street, New York City.-Limited free distribution

WHILE ROPE FOR MINING AND CONTRACTING is a 96 page catalog which contains not only the usual price list but also has many pages of data as to stresses in suspended cables, stresses in hoist and incline ropes, and specific recommendations as to grades and constructions of rope for various types of power shovels, cranes, and other equipment; as well as a paragraph on the causes necessitating the premature discard of rope. Broderick & Bascom Rope Company, 4203 North Union Boulevard, St. Louis, Missouri. -Gratis.

TELEVISION RECEIVERS FOR THE HOME is an illustrated catalogue which describes a table and a console model television receiver. both of which provide a full 8 by 10 inch screen image as well as synchronized sound for complete sight-and-sound radio programs, Allen B. DuMont Labs., Inc., 2 Main Avenue, Passaic, New Jersey.-Gratis.

ICE HOCKEY

A CASE packed with the thrills and interest of one of the fastest sports in the world and involving a well known sporting arena, has recently come before the New York State Courts.

The owner of Madison Square Carden filed suit against a moving picture producer and distributor, charging unfair competition arising out of a motion picture involving ice hockey In the complaint, the plaintiff pointed out that Madison Square Garden was a sporting arena constructed at great expense, and that it was designed so as to have a large ice hockey arena in which professional and amateur games could be played. The plaintiff also pointed out that he controlled one of the best-known professional hockey teams, the New York Rangers, who were members of the National Hockey League. In order to take moving pictures of hockey games played in the arena it was necessary to obtain plaintiff's permission. The plaintiff then charged that the defendant, knowing these facts, and knowing further that he would have to pay a valuable consideration in order to obtain permission to take moving pictures for use in a feature moving picture play, had produced a moving picture which, while it actually did not have any pictures of games in Madison Square Garden, contained -cenes purporting to show professional ice hockey games in New York City, and that many people were misled into believing that they were viewing games being played in Madison Square Garden. In order to encourage this impression on the part of the public it was also charged that the defendant incorporated in the moving picture, photographs taken in a Detroit arena during the Stanley Cup Series of the year 1936-1937, particularly showing plaintiff's team, the New York Rangers.

In its advertising circulars and literature, the defendant repeatedly referred to Madison Square Garden, and it was charged by the plaintiff that when these statements and references were read by the general public they believed that they were viewing professional ice hockey games played in Madison Square Garden.

The defendant made a motion to dismiss the suit on the grounds that the general charges made by the plaintiff in the bill of complaint, as summarized above, did not state a good cause of action. The trial court agreed with the defendant and dismissed the suit. However, on appeal the decision of the trial court was reversed and the appellate court held that the complaint stated a good cause of action. The appellate court pointed out that the plaintiff had built up a substantial good will in the name Madison Square Garden, and that it had also huilt up valu-

able property rights in the granting of licenses to take moving pictures of hockey games in Madison Square Garden.

Referring to defendant's moving picture the appellate court stated:

"The public would suppose, and actually did, that the background of the film was an authentic background presenting scenes of actual games in which the plaintiff's team participated in New York. Defendant's circulars referred of the arena as 'Madison Square Garden. Even in a story that is obviously fiction => far as its plot is concerned, defendants should not be permitted, by the unfair practices alleged, to violate and appropriate to themselves plaintiff's valuable property rights."

BELATED TECHNICALITY

DECHNICAL defenses are looked upon with disfavor by the courts. This is equally as true in suits for patent infringement as in other types of cases. In a recent suit for patent infringement, brought by a German corporation and citizen in the Federal Court in New Jersey, the patent in suit was held to be valid and infringed. The issues had been thoroughly considered both by the trial court and by the Circuit Court of Appeals on an appeal taken from the decision of the trial court. Thereafter the case was referred to a special master to determine the amount of damages and profits. At this stage of the proceedings for the first time the defendant raised the defense that the German corporation and individual had never actually appeared in the case and accordingly had not subjected themselves to the jurisdiction of the court. Plaintiffs had appeared in the case only by counsel.

The Court pointed out that where an attorney appears for a party in a legal proceeding it is presumed that he has authority from the party to so appear. It also pointed out that this is purely a technical defense and that the defendant should have raised it prior to the trial instead of waiting until after the case had been decided by the Trial Court and reviewed on appeal

BABY BATH

IN our complex civilization even babies be come involved in patent litigation.

In a recent case one of the courts upheld the validity of a patent covering a popular type of collapsible infant's bathtub identified by the name "Bathinette." The patented bathtub consisted of a collapsible support, a tub made of flexible material mounted on the support, and a dressing table pivotally connected to the support so that it could fold from a position overlying the tub to a vertical position exposing the tub. The defendant in the suit was originally licensed to manufacture bathtubs under the patent. However, prior to the institution of the suit the defendant had cancelled the license agreement and had continued to manufacture the bathtubs without the patentees' permission. The patentees filed suit for patent infringement and in the decision referred to above the court held that the patent was valid and that the bathtub manufactured by the defendant constituted an infringement.

PHOTO ELECTRIC

RECENT decision of scientific interest, involving the most widely used television system, has been handed down by the Federal Court for the District of Delaware. This decision holds that the well-known television pioneer Vladimir K. Zworykin is the inventor of the system. Aside from the fact that the court credits Mr. Zworykin with the invention of this system, the decision is of interest to inventors and to industry because it illustrates two important points. The first point is that applications are frequently kept pending in the Patent Office for protracted periods of time without any fault on the part of the inventor or on the part of the Patent Office, Mr. Zworykin's patent application was filed in 1923 and was still pending at the time of the decision due to the fact that it became involved in a series of interferences with the applications of other inventors claiming to have conceived the whole or part of the system described in the application.

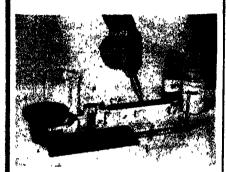

The second point illustrated by the decision is that while no new matter may be added to a patent application after it has been filed the patent application may be amplified so as to include matter which is obviously necessary and well known.

The photo-electric cell employed in the television system involved in the dispute consisted of a layer of aluminum foil, an intermediate layer of an insulator, such as aluminum oxide, and a layer of potassium hydride. In order to make the cell effective for television purposes it is necessary that the layer of potassium be formed of discrete particles electrically separated from each other. As originally filed, the Zworykin application did not specifically state that the layer of potassium was formed of discrete particles. However, it was subsequently amended so as to include a statement of this character. It was contended by Mr. Zworykin's opponent that the amendment constituted the insertion of new matter into the patent application and accordingly was improper. The Patent Office sustained this contention and suit was filed in the Federal Court in behalf of Zworykin. The Federal Court took a different viewpoint from the Patent Office. The Court found that at the time that the Zworykin application was filed the current literature showed that it was well known by those skilled in the art that the layer of potassium had to be formed of discrete particles. The Court also found that the current literature of the time showed that the only way known for making a photoelectric element of this character was by the process of depositing potassium from a vapor and that the potassium when thus deposited could exist only in the form of separate and discrete particles or globules. Under the circumstances it was held that the amendment did not insert any matter in the application but merely amplified it by including a statement of what was obviously necessary and also well known in the art at the time.

Experimenters-Schools-Field Workers

An Accurate Balance

at a price within the reach of all

Sensitive to 2/50 gram Weighs up to 100 grams Compact—No loose parts Modern, durable construction Small convenient size Handsome streamline design

Now permissible for auxiliary use in drug stores (N. Y. C. Serial B17.)

Never before a balance with all these exceptional features!

Finest Quality-Made of tested materials Its construction will appeal to laboratories desiring the best equipment. The Bakelite cup is unaffected by practically any substance that can come in contact with it the tool steel knife edge and agate bearing will give long life and ac-

Fatreme Sensitivity-Weighs to one decimal point farther than the usual lowpriced counter scales and serves nearly every laboratory purpose short of precise analysis The capacity of 100 grams is ample for the delicate weighings made in the usual course of teaching, organic synthesis, experimental work, compounding, photographic work, etc

Compact-Convenient-Does not monopolize a laboratory table. Placed on the desk of the busy technical executive, it will soon become indispensable

Its small size makes it possible to carry it on inspection and testing trips at a distance from the laboratory. It is small enough to be carried under the arm or in an overcoat.

Graduated in either the Metric System (grams) or the Apothecary's System (grains, drams and ounces) In ordering, please indicate which of these you desire.

LIQUID...volatile...powerful ..tetraethyl lead has a mysterious and valuable effect upon gasoline. Just a small quantity added to a gallon of gas improves its anti-knock value. It acts to prevent the power-wasting "knock" or "ping" that years ago might well have throttled the development of the modern automobile's high compression engine

Today tetracthyl lead is the active ingredient of the anti-knock fluids used by oil companies the world over to improve the anti-knock quality of their gasolines. This enables car owners to take advantage of the high compression engines built by the automobile industry in recent years.

Today every car has 3 grades of performance Because there are different grades of gisoline sold today, your car has different grades of performance,

depending on the gas you buy and your spark setting. Use the chart below to help you make your choice

BEST PERFORMANCE—with gasoline marked "Fthyl" on the pump or globe. It is highest in antiknock and all-around quality, Contains enough tetraethyl lead so that your engine's spark can be fully advanced for maximum power and con-omy without "knock" or "ping"

9000 PERFORMANCE with "regular" gasoline which permits the spark to be considerably advanced without "knock" or "ping" Most "regular" gasolines now contain tetracthyl lead, as shown by the "lead" signs on the pumps

POOR PERFORMANCE — with low-grade gasoline, poor in anti-knock quality. With low-grade gasoline in a modern car, the engine's spark must be retarded-which means loss of power and economy

TUNE IN ON "TUNE-UP TIME"

featuring Walter O'Keefe, Andre Kostelanetz' Orchestra Kay Thompson and Rhythm Singers . . . Thursdays . . . Columbia Broadcasting System, 10 p. m , Eastern Standard Time

A MAESTRO OF POWER

SWIFT and responsive as the strings and brasses of a great orchestra, power moves beneath this man's finger tips. Electric power, varied at his will from the crashing force of ten thousand sledges to the delicate pianissimo that pares a hairbieadth from a piece of steel. And so, from the machine that obeys this man's bidding rolls forth the symphony of American industry—more goods for more people at less cost.

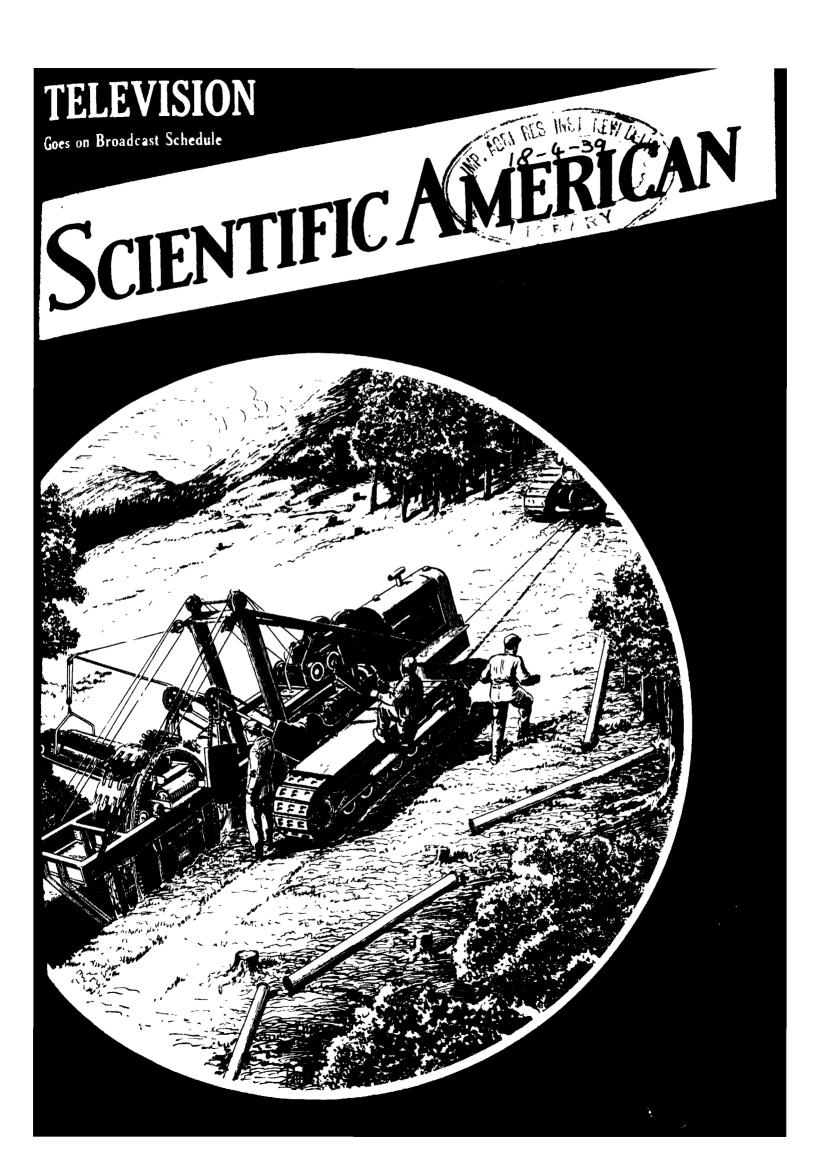

This man is typical of the millions of American workmen who, with the machines they direct, set the tempo of American industry. Today the mechanical power in the hands of each factory

worker is four times what it was 50 years ago As a result, the amount that each worker can produce has more than doubled. And because he produces more, he has more.

That is why five out of six American families own radios, why four out of five have automobiles, why one out of three owns an electric refrigerator. That is why America has today the highest standard of living the world has ever known. And General Electric scientists, engineers, and workmen, by applying electric power to the machines of industry, have done much to make this progress possible. Their efforts today are directed to the task of bringing about still higher living standards.

G-E research and engineering have saved the public from ten to one hundred dollars for every dollar they have carned for General Electric

Stepping Stone To The Future—

Since science touches and influences our lives hundreds, thousands of times daily, we can be best prepared for the future, can best profit by the achievements of science which will continue to influence and change our lives, our businesses, and our whole

economic scheme by carefully following current progress. Understandable, thorough, and authoritative discussions of trends and how they will affect us are presented by experts in many fields of pure and applied science in each monthly issue of

SCIENTIFIC AMERICAN

Vital From the laboratories of the world, from our vast industrial empire, from agricultural frontiers, scene of the uniemitting fight against insect pests, drought, and Nature's other hazards, from far-flung outposts of civilization where man ventures, explores, digs into the secrets of man's past and attempts to discover who and why and what we are; from every site of man's attempt to know himself, to help himself, and to progress—from these sources comes the vital news of achievement presented each month

Authoritative Noted scientists and experts in many fields of endeavor write for each monthly issue. Authors are carefully chosen both for their intimate knowledge of their subjects and for their shiltly to write "humanized science" articles. In addition to the office staff headed by Orson D. Munn, a staff of contributing editors assists in checking and cross-checking every

Understandable Second only to wide general interest, in importance, is the style of Scientific American articles. They must be written so that the layman can easily understand them. This is assured by the care with which the editors select authors and material. The editors attend scientific and industrial meetings, make periodical survey trips, and get suggestions as to

Readers Thinking people—progressive industrialists, educators, ambitious laymen, thousands of industrial executives, technicians, research engineers, scientists, alert men who lead the nation and mold its industrial future—these are the present readers of Scientific American. Many of them laid the groundwork for their careers by reading this journal regularly, and continue to read it for its institution.

by Scientific American And "vital" is the word, for the findings of science are as important to you as are the treasures it has already heaped in your lap—your car, telephone, radio, electric lights, your longer span of life! Scientific American tells the facts (and interprets them) about scientific and industrial achievements which will continue to change civilization. It provides practical, usable knowledge; inspires further achievement, and gives mental stimulation. Scientific American keeps you alert and up-to-date.

fact. This list of contributing editors reads like a "Who's Who" of top men in Science and Industry, and includes Directors of Research of several gigantic industrial organizations, the editor of the Journal of the American Medical Association, a noted naval captain, a number of famous university professors, and others. These men are, in effect, continually "in conference" with the office staff.

both authors and material by reading each month thousands of publications scientific, technical, and trade magazines, and institutional, industrial, and governmental bulletins. The result is a clear, straightforward presentation of editorial matter that is a happy compromise between the too-popular and the too-technical. Sensational writing is avoided; and facts take precedence over futuristic, illogical predictions.

IN digging trenches for pipelines which will transport oil, as described in the article starting on page 212 of this issue, a ditching machine is employed. As our front cover illustration shows, this machine frequently is used on such steep slopes that even the crawler-mounted machines are incapable of negotiating them under their own power. To help them up the slopes a cable is run to a winch mounted on a tractor which is securely anchored to a tree.

50 Years Ago in . . .

SCIENTIFIC ANDERTORN

(Condensed From Issues of April, 1889)

EMPLOYMENT 'Frequently one sees appalling computations of the vast number of workmen who are constantly thrown out of employment by new mechanical inventions that take the place of human hands. But along with the displacement of hand labor there has gone a replacement, in consequence of the increased production that always follows a cheaper process of manufacture. It must be admitted that though mechanical inventions have put a great many persons out of work, they have also put a great many more persons into work."

UNDERGROUND WIRES—"The work of removing the actual telegraph, telephone, and electric supply lines in this city, with a view

to forcing the electrical supply companies to use the subway system in such streets as contain it, has been vigorously prosecuted during the past week. A very impressive feature of the operations is the comparative darkness to which the city in these parts is relegated at night. The gas lamps are quite unable to supply sufficient light for the people, who have now been accustomed to electric illumination. It is to be hoped that the electric light companies will make every effort to start their lamps anew and give the many centennial visitors a good illustration of subway electric supply and illumination."

BLACK SNOW—"At Airken, Minn, on April 2, at 1.45 o clock, it became so dark that lights were necessary in business houses, and the air was filled with snow that was as black and dirty as though it had been trampled into the earth. Six ounces of snow and one-fourth ounce of dirt and sand were found in the bottom of a dish. The dirt is very fine, something like emery, and contains particles that have a metallic luster. This dirty snow fell to the depth of half an inch. The atmosphere at the time presented a peculiar greenish tinge."

TRANSATLANTIC—"The new and magnificent ocean steamer City of Paris arrived at this port on the 11th inst, on her first trip, having made the voyage from Queenstown in the remarkably quick time of 7 days, 11 hours, 39 minutes. It is believed her speed will be increased after a few more voyages have been made and her machinery becomes a little worn. As it was, the vessel made 498 miles as her tastest single day's run."

NIAGARA — There have been recently two very heavy falls of rock at Niagara Falls. At first a mass of rock fell from the Horseshoe Falls, and twenty-four hours later another mass was precipitated into the abysis below ... The result of the displacement is a change in the shape of the fall. Formerly the Canadian portion of the fall could be described as a horseshoe; but the breaking away of rocks in the center some years ago made it V shaped. Now that a further displacement has occurred, the fall has returned to its old condition.

DIAMOND—'The 'Iulius Pam' diamond, which is valued at from 15,000 to 20,000 pounds, has arrived in London from Kimberley It weighs 211½ carats, or fully 90 carats more than that other beauty, the Porter-Rhodes diamond, and was found in the New Jagers fontein United Mine. — The only larger diamond in existence is the Imperial, but it is said to be inferior in quality to the 'Julius Pam'."

ELECTRICITY—"Professor Elisha Gray remarks that electrical science has made a greater advance in the last twenty years than in all the 6000 historic years preceding. More is discovered in one day now than in a thousand years of the middle ages. We find all soits of work for electricity to do We make it earry our messages, drive our engine, ring our door bell, and scare the burglar, we take it as a medicine, light our gas with it, see by it, hear from it, talk with it, and now we are beginning to teach it to write."

TELEPHONES—"In probably no country in the world has the tele phone come into more general use than in Sweden. Not only can stockholm boast the most perfect telephone arrangements of any capital, in addition to the largest percentage of telephone subscribers, but the east coast and the west coast will soon be in telephonic communication, a line between Stockholm and Cothenburg being in course of ejection."

RECTIFIER—"A device which may be of considerable value is described by M. Neyreneuf in the Journal de Physique as an electric valve, by means of which the current can be sent in one direction, but not in the other. With a voltameter constructed of two aluminum electrodes, dilute acid as electrolyte, and an alternating current, he found that pure hydrogen was evolved at both electrodes, but on making up an arrangement with one electrode of aluminum and one of mercury, the current was found to pass in one direction only?

SWAY-. "The oscillation of high structures in storm winds is a much observed fact, and has probably been the cause of many failures in high chimneys by collapse or permanent set out of plumb by excessive pressure from the rocking motion set up in gales of wind... The Eiffel tower will no doubt be affected to a marked degree by high winds. Although its form of structure is of the least area to the force of the wind, its form and elastic material favor large oscillation in storm winds."

TEAK—"So indestructible by wear or decay is the African teak wood that vessels built of it have lasted fully one hundred years, to be then broken up only on account of their antique mould or defective sailing qualities."

AND NOW FOR THE FUTURE

Chafety factors in an transportation that have been made possible by scientific research.

Big in Value

...Little in Cost

Few things give you so much convenience, happiness and security—all rolled into one—as your telephone.

Telephone service is not only exceptionally good—it's cheap.

Nowhere in the world do people

get so much service and such good service at such low cost.

Experienced management, trained people and good equipment are three important reasons for this fact.

BELL TELEPHONE SYSTEM

OUR POINT OF VIEW

More Tax Diversion

EACH year the 10 percent excise tax on sporting arms and ammunition, levied under the Pittman-Robertson Act, is supposed to be ear-marked for use by the various states for wildlife restoration. Because it would assist restoration or restocking of game, sportsmen have not looked upon the Act with disfavor

It appears now, however, that somebody in Washington has had a brilliant idea: diversion to other uses of more than two thirds of the revenue obtained under this Act. Reliable estimates of this revenue place the full amount at \$3,250,000. Yet the recommendation for the appropriation to the states, when recently presented to the 76th Congress, was just \$1,000,000. Where is the other two and a quarter million? Going to build a post office for some tank town, or some other political extravagance?

To us, this attempted expropriation of moneys for other than their legal purpose is reprehensible in the extreme, and we therefore repeat here and wish to emphasize statements in the report of the House Committee on Wildlife Restora-

"The Committee is of the opinion that by proper administration and intelligent co-operation the Pittman-Robertson Act can be made the beginning of a national wildlife program, which if carried out to the fullest extent possible under the law can prove as beneficial to wildlife restoration and management as the Federal Aid Highway Act has been to the State highway systems of this country.

And it is our earnest recommendation to the Congress that the present excise tax on arms and ammunition be continued and that the full amount of the tax so realized be appropriated in the future for use under the provisions of this act " -FD.M.

Who Profits Most?

TIME and time again this page has pointed out the necessity for retaining the profit motive in the patent system of the United States. So have, also, many other authorities on patents and inventions. Yet we have before us the spectacle of a Congressional Committee, supposedly impartially investigating monopolies, indicating by many of its questions to witnesses an attitude prejudicial to the taking of a profit from an invention by the developer. Were this belief in the "guilt" of inventors confined strictly to the Committee, no great harm would be done; but, unfortunately, the members are, ex officio, authorities on this

subject and their words have the force of propaganda to sway the unthinking portion of our citizenry. Already, newspaper reports of their investigations of several industries have aggravated the too general, erroneous feeling that industrial patent holders are not to be trusted

As a recent witness for the 'defense' before this Committee, Dr. Vannevar Bush, president of the Carnegic Institution, was most effective. Taking from his pocket a little strip of metal about an inch and a half long, he explained that one company had spent \$100,000 to develop it. Warmed by the heat of his hand, it performed with a snap, it is a thermostat for use in electric irons and other appliances. At this enormous cost, it goes without saying that no individual or company would have developed it without the assurance that the patent law permitted a profit on its manufacture and sale. It is equally obvious that research of the kind that made it possible would be quickly and entirely abandoned by corporations should the present 17-year patent period be sharply cut or if general licensing of patents were compulsory under the law.

This seemingly simple yet costly development is but one of thousands made every year, also at great cost, in the interest of the public's comfort, convenience, and general well being. It is the people who benefit, even though the developer does make a profit for a few years. It is the people who must understand this fact and, knowing that the greatest profit is thens, take a determmed stand against unstudied modifications of the present patent system F D M

Resources

RECENT plea by the Administra A tion for a survey of the natural resources of the nation strikes a responsive chord in the editorial heart of Scientific American. But at the same time it creates a feeling of apprehension that will not down We have always been in sympathy with efforts directed toward conservation of lumber, coal, metals, and so on, we have given active editorial support to further the cause of those striving intelligently to this end. But we have seen the results of all too many governmental survevs---a new bureau set up, millions of dollars spent in field work and for endless reports that might well have been written in the reference room of a public library And then silence.

It is not too naive, we hope, to cling to a straw of optimism and to dare to look forward to the time when a lavishly en-

dowed government bureau will produce a plan that can be handed to the people of the nation to serve as a guide to coordinated conservation. It must be admitted that such a guide, if properly prepared by competent specialists, would be of tremendous value to industry, agriculture, and the public as a whole.

We do feel, however, that the same end can be reached—more economically, more efficiently, and in the same length of time-by those whose best interests will be served in the long run by the application of conservation principles that are well known today. This statement is made in no spirit of laissez-faire, but rather from a knowledge of how indus try in general is meeting and solving its own problems to its own and the public's advantage. Some scandal mongers and mud slingers to the contrary, this nation is no longer ruled by robber barons whose only aim is to despoil for their own benefit, and the devil take the hindmost Modern industrialists realize full well that our natural resources are not unlimited; that they profit most when they apply conservation tactics to the full Modern agriculturists are working along the same lines. The public is on the receiving end and is reaping the benefits And these benefits are accruing with a minimum of drain on the national treasury, a fact that will not be true if the Administration goes too far in its laudable but perhaps misguided efforts to study the whole problem of conservation. The money so spent might better be left in the hands of those who would apply it to practical methods of conservation rather than to the formulation of theories that make fine reading but are lacking in value when put to test.

It may help to clinch our argument if we cite a generalized example of conservation practiced for the much-kicked around profit motive. Years ago far-seeing lumbermen came to realize that stands of timber were not inexhaustable, that they could not ruthlessly cut down trees and leave the countryside a barren waste. They found that indiscriminate logging was not the profitable way and that it would interfere with future gain. So, just as any sensible business man would do for his own protection, they began to plan their operations on a conservative basis. Selective logging and tree-planting programs were inaugurated and, as these practices are applied more and more, we have little to fear for the future of this important industry that is tapping but at the same time replacing one of our important natural resources.

-A. P. P.

Personalities in Science

TO Dr. Edwin Hubble, of the Mount Wilson Observatory, in California, recently was awarded the Bruce Gold Medal of the Astronomical Society of the Pacific, 'for distinguished services to astronomy." Within the past decade Di Hubble has become an astronomer of outstanding world recognition.

On the occasion of the presentation of the medal Dr. Harold D Babcock, president of the Society, gave an account of his career and accomplishments, a part of which is quoted from the Society's *Publications*

'Dr Hubble was born at Marshfield, Missouri, November 20, 1889. His undergraduate studies, emphasizing mathematics and astronomy, were completed in 1910 at the University of Chicago, where, against spirited competition, he won a Rhodes Scholarship, a recognition of his promise for the future. The ensuing three years of study at Oxford, centered in the field of law, were followed by the degree of Master of Arts in 1913. On his return to the United States he was admitted to the Bar, but he soon found that his strongest interests remained in science. He resumed the study of astronomy at Chicago, became, in 1914, an Assistant at the Yerkes Observatory and a pupil of Professor Frost, and in 1917 received the degree of Ph D

Enlisting in the infantry that same fateful year, he served until 1919 in France, was mustered out with the rank of major, and immediately joined the staff of the Mount Wilson Observatory Here he rapidly made a place for himself in his chosen field, as testified by his receiving the \$1000 prize of the American Association for the Advance ment of Science in 1925, his election to membership in the National Academy of Sciences in 1927, his selection as Halley Lecturer at Oxford University in 1934—a rare distinction for any non British astronomer-and the award to him of the Barnard Medal in 1935.

"Even before he received his degree, llubble showed evidence of his skill as an observer. On taking up his researches at Mount Wilson, he boldly attacked the vast problem of determining the scale on which is constructed that part of creation within the range of observation.

EDWIN POWELL HUBBLE

Aided by the best equipment thus far available for the purpose, he has been able to establish new outposts of knowledge through the application of accepted methods and of new developments in technique

Dr. Hubble was the first to establish a reliable scale of distances for objects observable with the 100-inch reflector and farther away than the Magellanic Clouds. He has brought within the domain of the measurable a sphere of radius 500 million light-years. The volume of space now subject to exploration is a thousand million times as great as that amenable to quantitative discussion only 20 years ago"

After describing Dr. Hubble's researches on the Andromeda Nebula, made prior to 1929, which provided "almost conclusive evidence in support of the island universe hypothesis"—ob-

servations which "alone would attract the interest and respect of all astronomers"-Dr. Babcock refers in summary to the cosmological significance of his observations in general, "They certainly have reacted strongly upon the thinking of the greatest theoretical physicists and astronomers, have stirred the depths of philosophical speculation, and, perhaps more important than anything else, have clearly shown the need for still greater instrumental power. It is not an overstatement to say that the convincing data assembled by him with the 100-inch telescope have been a powerful argument for the construction of the 200inch reflector "

Dr. Hubble is the author of a recent book, "The Realm of the Nebulae," embodying in semi-popular form the results of his researches in the subject of his specialty.

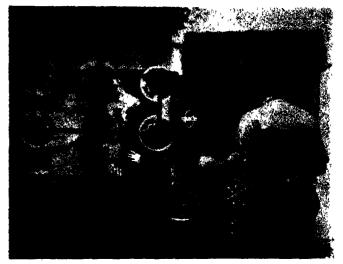

A MAGNIFICENT TIDAL FRONT IN A CHINESE RIVER

BY rising more rapidly in the seas than they can flow into adjacent land channels without producing an uncommonly steep front, the tides in a few suitably situated places on the earth produce bores, especially when sun and moon conspire to produce maximum rises A bore (old Scandinavian word meaning "wave") occurs in the narrowing Bay of Fundy, also in several English rivers. The bore shown

above is a heavy one which occurs at flood tide in extreme eastern China, near Hangchow, on the Tsientang. The bore rushes up the river at quite considerable speed, raising the water level many feet, mainly at the steeply shoping face. The standing figures on the distant bank give the scale. The fury of this thundering "wall" of swift, turbulent water is awe-inspiring and the natives never tire of witnessing it.

In a television studio. Left. Directing a scene on a "live" stage. Two cameras are used to introduce variety in the angles of view. Right: Another stage setting showing, in the foreground, the latest type of lighting equipment used in television studio work.

HERE COMES TELEVISION!

Will Serve Entertainment Needs . . . Technical Equipment Has Limitations . . . Standards Laid Down to Prevent Obsolescence of Receivers

By O. B. HANSON Vice President and Chief Engineer National Broadcasting Company

NOR years people who knew of my connection with television have been asking: "When do we get it?" Whenever the temptation to predict grew strong within me, I would mentally turn the pages of old magazines—"Television Comes to the Home" (1928), "Television Gets Ready for Business" (1930), and so on-then mutter a few incomprehensible phrases and let it go at that. Now I am in happier circumstances. Broadcasting of regular television programs to the metropolitan area of New York will start in April. The same time has been chosen for marketing the first commercial receivers. Together, the two events mark the real beginning of American television.

It is probable that the average intelligent reader, having scanned a few magazine articles and news stories about television, has arrived only at the point of confusion. Perplexing questions pop into existence, speculation arises, and nobody seems very certain of anything about television. Television is bound to have profound effects on our social order. It will affect existing industries, create at least one new one. Some day it may encroach on other entertainment and educational media. Perhaps it will cause a change in the styles of presen-

JUST prior to the arrival of scheduled television programs on the American scene, we present the accompanying article to give a comprehensive view of the situation as it stands today. Written by Mr. Hanson at our request, it clears up many misconceptions about the subject — The Editor.

tation that will be used in other media.

Will there be national television networks? What about the movies and television? Who will appear on the television screen and what will the programs be like? And what is television and how

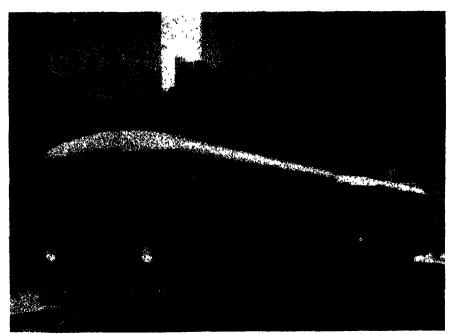

does it work?

Let me begin with the last question. A convenient definition of television is "the transmission of scenes or images in motion, by electrical communication methods." Broadly, it is a radio medium designed for the entertainment and education of the home audience. The television system which has gained widest acceptance is entirely electronic, without a single moving mechanical part. Its bright, moving images are in black and white, filled with interesting detail

and without a trace of flicker. The transmission apparatus, although almost infinitely complex in design, is entirely reliable. In a recent demonstration at Washington, D. C., in which the NBC mobile television units were the transmitting station, not one minute was lost in more than 30 hours on the air through equipment failure. I assume that the commercial receivers soon to be marketed will also be reliable and simple in operation

MY description of television's apparatus will naturally veer toward the technical And since I am most familiai with the NBC equipment, I shall use it as an example. Our apparatus embodies the RCA all-electronic system of television. In the camera, fitted with a photographic lens system, the light image is focused on a photo-sensitive mosaic inside the Iconoscope, a highly evacuated tube shaped somewhat like a dipper. The photo image is here registered and its light values converted to electrical potentials. We have here a "picture in volt ages," which, to be useful, must be analyzed, taken off the mosaic, amplified, and broadcast

The analysis, or "scanning," is accomplished by a beam of electrons originating in the neck of the Iconoscope and focused on the mosaic to the fineness of a pin point by an electrostatic lens. The beam is drawn across the mosaic, by horizontal and vertical deflection coils, in a predetermined pattern of 441 lines at the rate of 30 frames a second. Actually the rate of scanning is 60 half-frames, or "fields," per second. Interlacing—scanning of the odd lines dur-

Mobile television unit consisting of two trucks that carry all equipment necessary for relaying television programs from remote points to the main transmitter located some miles away

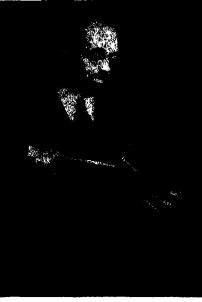

ing the first field, followed by the evennumbered lines in the second—completely eliminates flicker

In so scanning the mosaic, the electron beam neutralizes the charge that has accumulated on each element of the mosaic. In so doing, the beam sets a current flowing in the circuit; in aggregate, these impulses constitute the vision ("video") signal. They are amplified many times and sent to the transmitter either by radio relay or coaxial cable, where they modulate the station's ultra high frequency carrier before being broadcast over a specially designed wideband-pass antenna system

At the receiver, after again being amplified, the video signal modulates the electron beam in the neck of a large funnel-shaped vacuum tube called the Kinescope. The modulated beam is drawn over a fluorescent screen of zinc sulfide at the large, or screen, end of the tube in the predetermined pattern of 441 lines, 30 times a second. And since the light values created in the fluorescent screen vary directly with the intensity of the electron beam, a replica of the original image is produced. Viewing is either direct from the end of the tube or by reflection in a mirror.

This is the system we shall use in inaugurating our television program service in the New York area. We are confident that with the inevitable technical improvements that will develop once a television service gets well under way, the system will serve the needs of the American people.

Our technical facilities at W2XBS include studios for both live talent and

Mr. Hanson, author of the accompanying article, with one of Iconoscope tubes used in transmission

film programs, and a mobile television station for outside pick-ups. This latter should be of great assistance to us in presenting programs from athletic stadia, parades, and sidewalk interviews, and all types of outdoor news events, in addition to floor shows from popular night clubs and hotel grill rooms. We shall use either our present mobile station, or one similar to it, in televising the next Presidential Inauguration in Washington, D. C.

Our studio for live talent programs is fitted with three Iconoscope camerachains for multiple camera pick-up of performances. This assures the variety of shots necessary in the pictorial art. Switching from one camera to another is done in the studio control room by means of push-buttons. Several projec-

tors and cameras are located in the film studio.

All technical equipment has its limitations. Television apparatus offers no exception. Our camera's depth of focus still leaves something to be desired, although improvements are constantly being made in this respect. Likewise, the spectral response of the Iconoscope is not equivalent to that of the human eye, though its range is considerably greater, since it extends into the infra-red frequencies.

In a more practical sense, television service at present is limited to a few transmitting stations. NBC has been broadcasting intermittently with the RCA all-electronic system of television since June, 1936. Several other stations employing the electronic system, how ever, will soon be broadcasting. One other station is licensed in New York City, another in nearby New Jersey and two others upstate. Bridgeport, Connecticut, will be the location of a sixth eastern station. Most of these will be isolated stations, although I believe the two in upstate New York will be interconnected by radio relay

THIS brings us squarely against the problem of television networks. If television is to fulfill even a small part of its promise it must create networks Spontaneity will be the life blood of tele vision, and it cannot deliver news events to viewers in many cities, while they are still happening, without building net works. Eventually, I am sure, the country will be covered with such networks in much the same manner as radio net works reach into all parts of the United States today. Economic considerations also make the creation of such networks imperative, but technical and cost problems still limit our progress in this direction Most circuits comprising our national sound radio networks cannot transmit sound frequencies beyond 5000 cycles. Good television demands circuits capable of transmitting a band of frequencies from 30 to 4,000,000 cycles per second for the video signal alone.

Two methods are available. The coaxial cable, a concentric conductor capable of passing the wide band of frequencies used in television, is apparently the new art's equivalent of the wire circuit used to interconnect sound broadcasting transmitters. One such experimental circuit, connecting New York and Philadelphia, is already in existence, although some modification of it would be necessary if we were to transmit 441line images over it. Its cost, I understand. was about \$5000 a mile. The other possibility for networking is the use of automatic beamed micro-wave radio relays which, in tests, have given us reason to suppose that they will be at least an important element in the final answer to television networking questions. Neither

of these is in existence in any practical sense, nor is either likely to be available for any national network for some years to come. However, the availability of a limited micro-wave network along the castern seaboard is a distinct possibility before the Presidential Inauguration of 1941. The probabilities are that, for at least a decade, television will be confined to more or less isolated stations.

located in the larger centers of population, and serving perhaps a little more than 50 percent of our population.

Another very practical limitation is found in the frequencies used in television. Because of the necessity of transmitting a vast amount of information within an exceedingly short time, the developers of television had to turn to the ultra-high frequencies-waves between ten meters and one meter in length. This brought some decided advantages, it also brought some disadvantages, the chief of which is the fact that the range of high-quality reception is practically limited by the visual horizon as seen from the transmitting antenna. The NBC transmitter, with its antenna on the very top of the Empire State Building, highest building in the world, reaches out about 55 miles, although pictures have been received up to a distance of 100 miles. Perhaps when we have learned more about tube design and can obtain greater power output than the present 30,000 watts peak we shall extend our service range. That is a matter for the future to decide

ON the other hand, within the service range an excellent signal is laid down. Ordinary static is not present on these frequencies but man made static, such as is created by diathermy apparatus, electric razors, and faulty automobile ignition systems produce interference that is detrimental to television reception. Future laws may require the installation of suppressors on all electrical equipment radiating energy that interferes with television and all other communications service on the ultra-high frequency bands.

I have emphasized some of the problems of ultra-high frequency transmission. I hope that I have not given the impression that they are of such gravity as to ruin television's chances of success. In my own home, about 46 miles from the Empire State tower transmitter, I enjoy the reception of excellent images. I am quite sure that everyone within the metropolitan area of New York who invests in a receiver and has it properly installed will also enjoy a unique type of entertainment.

This brings up the question of the type of entertainment television will probably offer in the near future. Today's television, as I have indicated, is capable of broadcasting studio productions by live

Title of the first hour house of the partition of the face of

Right: A television receiver of the type that will be available for home reception of sight and sound by radio. The image is viewed in a slanting mirror in the hid of the receiver Below. Rear of the receiver, showing the funnel shaped shield of the cathoderay tube (Kinescope) that makes images visible

talent, motion picture film, and outdoor programs relayed by a mobile television station. A single production, in fact, might embrace all three types. In the past we have successfully combined action in our live talent studio at Radio City, films of outdoor scenes and still pictures from a projection room, and special effects from yet a third studio into one production.

The NBC television program staff, under the direction of Thomas H. Hutchinson, has been experimenting for two years and more with numerous types of material. Some, conspicuously successful in other media, have been found to he dismal failures in television. Others were found to have television qualities; all needed adaptation. What is required is a rather fast pace, an ease of performance, and a certain spontaneity that registers well in television. Up to the present we have found no accurate yardstick that will measure in advance the success of any given act or performer on television.

During the experimental period, Hutchinson's staff has put on a variety of plays, motion pictures of all types, educational material, vaudeville and nightclub entertainment, orchestras, and what not, Magicians, jugglers, trained dogs, a scientist showing the microscopic life in a drop of water, a book reviewer, legitimate actors and educators have tried their talents on the new art. The individual items have run all the way from an individual turn of ten minutes or so to dramas and fashion shows of 35 minutes or more. We have put on sidewalk interviews, both day and night, picked up a floor show in a nearby cafe, and televised the graceful gyrations of skaters on an outdoor rink. We have covered a spectacular fire.

These are beginnings only, but I believe they offer promise that television programming will develop into something both highly interesting and informative. Certainly no other medium will be able to compete with television in furnishing programs of news events. Television will be on the spot and will flash the scene into the home while it is still happening; when the program begins neither the engineer behind the camera nor the viewer at his receiver will know what the outcome will be.

But what about television's effect on the motion-picture industry? The motion picture, like all theatrical entertainment, is of mass appeal; an audience must be present in large numbers to get fullest enjoyment from one of the theater's spectacles. Much of the appeal, therefore, is social; going to the theater or the motion-picture house is a social event. The wife wishes to dress and get away from the home scene for a few hours, to mingle with hundreds of others motivated by the same impulse. It is not likely that television, or any other medium that enters the home will ever

(Please turn to page 251)

Quicker Than the Eye

THE human eye is a pretty good pyrometer. In estimating temperatures that are high enough to bring about the emission of light, the eye has served the steelmaker effectively for at least 3000 years. Only within the past decade or two has it really begun to be taxed beyond its capacity as an aid in steelmaking

Considered as a pyrometer, or as a camera, or merely as a means of getting about in the world, the human eye has two serious weaknesses: it is slow, and it is easily fatigued.

Everyone who has dabbled in amateur magic and sleight-of hand knowshow easy it is to make quick movements that the eye cannot follow. Many steel-making operations are now so fast that it is impossible to follow them visually, at any rate to the extent that one could say afterwards that this or that part of the steel was too hot or too cold.

As for fatigue, look at a bright light or toward a window, and note how the outline persists after the eyes are closed. Or stare at an intermittent colored sign and note the complementary color that appears momentarily as the lights go

out. These effects are but momentary, but they can be cumulative, who has not felt the depressing effect of overex posure to bright sunlight or to the flickering movie screen? Modern steelmaking processes, at least those that are operating continuously, can no longer be controlled by casual and occasional inspection. They have to be watched, persistently, and the human eye just can't take it.

At this point the photo electric cell steps into the breach and provides an eye that is in some respects as sensitive and also as discriminating as our own but at the same time is much quicker and much less subject to fatigue

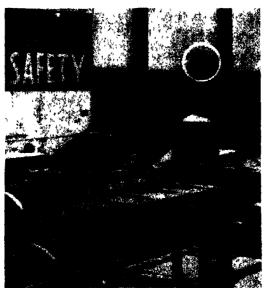

Two types of photo-electric cell have found use in pyrometry. One of these is the cesium vacuum cell, requiring an applied voltage, familiar to all amateur and professional experimenters with electron tubes. The other is the type used in large numbers by camera enthusiasts in their exposure meters. This is the Photronic or barrier layer cell, a self-generative type of photo-electric cell which requires no applied voltage.

Demand for Better Steel Has Made Necessary More Careful Control of Processes . . . Photo-Electric Cell Measures Temperatures Accurately

By ROBERT B. SOSMAN, Ph.D., Sc.D.

Research Laboratory, United States Steel Corporation

In the cesium cell the external voltage is supplied by a storage battery or recti fier, when light falls on the cell the variations of current in the circuit can be used to indicate and record the temperature of the hot surface from which the light came. In the self-generative type of cell, a metallic plate is coated with a mixture of seienium and other substances. This layer in turn is coated with a layer of vaporized metal so thin that it is transparent. One electrical connection is made to this layer and the other to the metal plate. If a meter is placed in the circuit and the light from a hot object is allowed to fall on the cell, the current in the circuit will be in proportion to the light intensity and again we have a means for indicating and recording the temper

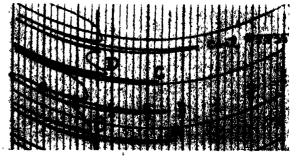

Above, in circle: Photronic photo cell mounted above a roll table in the strip mill at Fairfield Works of the Tennessee Coal, Iron, and Railroad Company. Right: A sample of slab-temperature record made by a Photronic pyrometer on a strip mill

ature of the surface from which the light

An application of the cesium photoelectric cell to the steel mill is in the so-called "Optimatic" pyrometer, mount ed to read the temperature of the fast traveling strip of metal in a modern hot strip mill. This mill takes a hot slab of steel and converts it at steadily in creasing speed into a ribbon hundreds of feet long and several feet wide, which is later cut into sheets for tin cans, auto mobile fenders, and innumerable other uses. So much depends upon proper temperature in the strip, as well as proper speed, roll pressure, and tension, that the estimation of temperature by the unaided eye is no longer dependable

The Optimatic pyrometer has a matched pair of cells, but does not use the pair in quite the same way as we use our own pair of eyes. It looks down on the hot surface of the strip with just one eye, while it cocks the other eye toward an incandescent lamp. Through the operation of a set of electron tubes the current in the lamp is caused to change until the lamp matches in brightness the hot surface, and the lamp curient thus serves as a measure of the temperature. All this takes place much quicker than I can tell about it, and the record of temperature is made within a fraction of a second after the pyrometer sees the steel.

IN the Research Laboratory of the United States Steel Corporation we have preferred to depend upon the Photronic type of cell, and in this way eliminate some of the troubles incident

and the second control of the second control

to the use of a rectifier such as is necessary for the cesium cell. In one application, a Photronic eye, carefully water-jacketed to protect it from damage by heat, looks down upon the roll table along which the hot slabs for the strip mill begin their journey. When it is first seen by the pyrometer, the slab has already been given a squeezing and cleansing that gets rid of the coating of scale formed upon it in the heating-furnace. The slab is thus left with a clean, glowing surface whose temperature is instantly recorded by the electric eye.

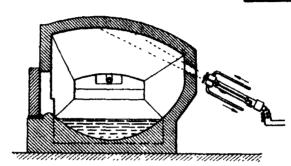

One of the illustrations shows a portion of the automatic record made by the pyrometer on a moving strip of paper. At the point A, the slab has just passed under the eye or receiver and has flashed its temperature, but was in sight for such a short time that it made only this single record of temperature. After several passes back and forth through the first set of rolls, however, it had lengthened out so much that it reached clear back again under the pyrometer and made a second record, B This time the greater part of it passed back under the pyrometer as the strip emerged from the rolls, then went forward again through the last pass, thus doubling its appearance on the record. If its temperature had been uniform and had not changed during this brief interval, it would have drawn a vertical straight line, but the surface is, of course, cool ing all the time and if uniform from end to end should make an inclined straight line. If hotter at the real end, on the other hand, it should make a "V". This was actually the case with the second tollowing slab, registered at C, when it came back to make its longer record, at D. These variations are nearly or quite invisible to the human eve but they tell men in charge of the heating and rolling a good deal more than they would tell you or me.

ANOTHER application of the photo-electric pyrometer, this time one in which absence of fatigue rather than quickness is its most valuable characteristic, is found in the so-called pyrometric roof control in the open-hearth furnace. This is a furnace into which cold scrap steel is loaded through wide front doors, to be melted down by a flame of gas, oil, or tar. After the steel is melted, liquid cast iron from the blast furnace is poured in, and the mixture 18 then held for several hours while refining takes place. In the refining action, the impurities are hurned out of the material and absorbed by the slag on top of the metal, leaving only pure iron behind.

The limiting factor in the speed of such a furnace is the melting temperature of the roof and walls. These are usually built of silica brick made from

sandstone or quartzite, the white rock that forms the high ridges of central Pennsylvania. These silica brick melt sharply at 3142 degrees, Fahrenheit, just as sharply as a piece of ice melts at 32 degrees, Fahrenheit.

In the presence of the vapor of iron and iron oxide that is present in the openhearth furnace, silica brick melts at a temperature lower than this, in fact, very close to 3000 degrees, Fahrenheit. The furnaceman dare not let his roof pass this temperature else it begins dripping into the molten steel below, forming "icicles" like those seen along a roof gutter during a thaw It is important that he get the furnace as hot as possible to gain speed in the process, yet he cannot stand in front of the fur-

Above: A roof-control photoelectric pyrometer mounted in the back wall of an open-hearth furnace. Left: Diagrammatic cross-section of one of these furnaces, showing how the pynometer is placed. A constant flow of water, indicated by the arrows, cools the pyrometer

nace peering through the wicket of the furnace door, for not only has he other duties to perform but his eyes would soon be so fatigued by the brilliance, even though protected by his colored glasses, that he would be unable to judge accurately the temperature of the roof His usual former practice, therefore, has always been to play safe and stay well below the melting temperature of his roof, even though he lost time thereby, because melting a roof is a very expensive accident.

With the electric eye always on the job, however, he can attend to his other duties and no longer be concerned about getting dangerously near the melting temperature. The pyrometer can be connected to an automatic controller which will shut off a part of the fuel the moment the roof temperature reaches the limit which has previously been set on the controller. Then, about one half minute later, when the temperature has dropped back through the prescribed lange of action of the controller, the fuel will again be automatically turned on.

In the open-hearth furnace, the pyrometer is arranged to sight through an opening in the back wall of the furnace upon the middle point of the inside surface of the roof. A record made by one of the automatic controllers shows that the temperature had repeatedly gone just above 3000 degrees but had been instantly pulled back by cutting off fuel, only to come up again a short time later. This really effective service, independent of human judgment, makes work possible at the highest temperature

without danger of destroying the furnace,

The pyrometer, mounted in the rear of the furnace, is protected by a steel jacket through which water constantly circulates, for it is uncomfortably hot in the vicinity and the electric eye is almost as sensitive as the human body to temperatures above 100 degrees. Constant circulation of cold water, however, keeps it in prime working condition for weeks or months at a time.

It need hardly be said that these devices have their little idiosynciasies which have to be learned by experience. For example, if you stood in front of an opening in the furnace wall as long as the pyrometer is expected to stand there, you would probably be stung now and then by a flying particle of molten steel or slag. These particles are projected up by the vigorous boiling that occurs in the steel bath, and occasionally one will fly on such a trajectory that it comes straight out through the opening. It will not do to try to protect the pyrometer by a shutter or screen, as that would cut off the necessary light from reaching the automatic eye. A piece of glass would stop the particle but the particle would stay where it stopped and the accumulation would gradually cut off the view. We want a screen which is transparent and always on the job to catch the particles, but one which will throw them away as soon as they are caught. A jet of altois the ideal screen for this job. It stops none the light but it deflects the flying particle and renders it harmless.

ern oil tanker, the S. S. J. W., Van Dyke, at night, Note I-protected passageway down the center of the deck

IL is found in widely scattered areas, with the richest deposits often hundreds and even thousands of miles from the great consuming centers. From the days of the earliest oil wells, therefore, the development of efficient and economical transportation from the wells to the consumer has been one of the major problems of the industry. The fact that the American motorist pays close to the world's lowest price for gasoline is to a considerable degree due to the success of the oil industry in adapting the various forms of land and sea carriers to the transportation of its products.

During the earliest days of the industry, the output of the wells was barreled and carried by wagons to the small local tefineries and from there to the nearest railroad siding. Except for some slight competition from canal and river car riers, the teamsters and the railroads enjoyed a monopoly on the haulage of petroleum, Today, the teamsters have disappeared. The railroads, on the other hand, continue to be an important factor, deriving a revenue of \$250,000,000 annually from the crude and refined products shipped by the petroleum industry. Their days of preeminence, however, are past. By far the greater part of the output of the wells is now transported by pipe lines, oil tankers, and motor tank-trucks.

Within the continental borders of the United States there are approximately 345,000 active oil wells, located in 22 states. Fifty-five thousand miles of pipe line gather the day's supply from the wells and carry it to the gathering sta-

THE MOTORIST

tions on the trunk pipelines. From the gathering stations, the oil flows through 60,000 miles of trunk line to 437 operating refineries in 28 states and to marine terminals at coastal points.

From the marine terminals, the crude oil is shipped by tankers to refineries in the United States which are not linked by pipe line to the oil fields, and to ports throughout the world From the refineries, the refined products are shipped by tankers overseas, and to distribution terminals in the United States by inland wa-

terways, rail, and more than 5000 miles of pipe line Forty thousand motor tank trucks carry the refined products from the distribution terminals to the nation's 200,000 filling stations.

TODAY, approximately 75 percent of all the oil produced in the United States is moved by water carriers at some stage of its passage from the well to the consumer. Practically all shipments to points along the Atlantic and Pacific coasts are made entirely by water From these receiving points on the two coasts, oil barges and river tankships carry petroleum products through 30 000 to 45,000 miles of waterways to inland destinations. During a single month, tankers have unloaded as much as 45,000,000 barrels of crude oil, gasoline, and other petroleum products at United States ports

The United States leads all nations in its contribution to the world's total of 1655 oil tankers of 1000 gross tons of over As of June 30, 1938, there were 418 tankers aggregating 2,759,642 gross tons under American registry, not including the oil barges and other craft of less than 1000 gross tons which constitute a big majority of the oil carriers that ply our inland waterways. Tankers constitute about one third of American merchant marine tonnage Petroleum and its products provide nearly one third of all water-borne tonnage in American world trade.

Ocean transportation of petroleum has progressed a long way since the first ship to carry a cargo of oil on the high seas sailed for England from Philadel-

plua in 1861. The vessel was the 224 ton brig, the Elizabeth Watts, and she carried her cargo in barrels. It was not until 1869 that the first oil ship fitted with iron tanks appeared. The name of this pioneer tanker was the Charles, a sailing vessel of 774 tons with 59 tanks Prior to this, the oil had been shipped in barrels, or entire holds of the vessels in the trade had been used as single tanks. The first steam tanker appeared in 1878, and by 1885 more than 1000 ships with a capacity of from 2500 to 14,000 barrels of oil were transporting American petroleum products to United States and foreign ports

Fver since the first tank-fitted ships appeared, the trend has been towards larger, faster, more efficient vessels. It is this search for speed and economy in tanker operation that is directly responsible for the introduction of welding in the construction of the larger vessels during recent years. Welding makes it possible, without sacrificing strength, to reduce materially the hull weight which must be moved by the ship's propelling machinery, while the smooth, welded hull offers less opportunity for surface corrosion.

One of the first all electrically welded. self-propelled vessels to be built I the United States was the White Flash, a tanker 201 feet 2 inches over-all, with a capacity of 7500 barrels of oil The White Flash was delivered in 1931, but it was not until 1936 that the same construction method was applied to the larger type of ocean oil-carrier. In 1936 The Atlantic Refining Company placed with the Sun Shipbuilding and Dry Dock Company an order for a tanker of 18.500 tons dead weight, in which the entire tank space extending from the engine room bulkhead to the forward end of the tank space was to be of welded construction The vessel was commissioned in February, 1938, and is now on the Philadelphia-Texas Gulf Coast run A sister ship, built for the same company in the same shippard, was completed and placed in service on the same run in August, 1938.

The two new tankers—the J. W. Van Dyke and the Robert H Colley—are the world's largest welded ships and illustrate in graphic fashion the remarkable development that has taken place in the construction of oil-carrying vessels since the first tank ships appeared nearly 70 years ago. The new tankers have an

Gets His Oil

Oil, Gasoline Distribution Relies On Science For Aid . . . Problem Has Inspired Unique Developments . . . Pipe Lines, Huge Tank Ships, Trucks

over-all length of 541 feet 5 inches. The capacity of each is 156,000 barrels, or 6,552,000 gallons - enough gasoline to supply the average requirements of 10,000 motorists for a full year.

Turbo-electric engines developing 5000 horsepower give the ships a speed of 13 25 knots, enabling them to make the trip between Philadelphia and Texas Gulf ports in six days. Three 300-horsepower discharge pumps, driven by 2300-volt explosion-proof motors, give each of the vessels a rated maximum discharge capacity of 630,000 gallons an hour. With adequate shore pumping equipment, each can be loaded in approximately eight hours.

At some loading points, particularly on the Pacific Coast, where shallow wa ter or lack of harbor facilities make it impossible for tankers to tie up to the docks, oil carriers take on their cargoes through submarine pipe and hose lines that may run a full mile out into the ocean. The vessel is brought into position, anchored, and made fast to buoys anchored to the occan bed. The submarine hose is hauled aboard and attached to one of the tanker's intake pipes. Orders are given by submarine telephone when it is time to begin pump ing in the oil When the loading is completed the hose is cast off, made fast to a buoy to mark its location, and the tanker sets out to sea.

Radio telephone communication between refineries located at tide-water and their tugs operating in the harbor is a recent development that speeds the handling of tanker cargoes. The tug-to-shore radio 'phone communication often saves many hours when a tug that has left the docks is needed in a hurry at some point in the harbor, and it is frequently possible to keep the tugs operating efficiently in thick weather that would otherwise slow them down or put a stop to their activities.

Just as the modern oil tanker is a skilful adaptation of the cargo ship to the transportation of a particular type of cargo, so the oil pipe-line is an equally skilful and efficient adaptation of a medium used for centuries for the transportation of water. For practically all liquids available in large volume, pipe lines provide the most economical form of land transportation that has ever been devised. The cost of transporting petroleum products by pipe line is approximately half the cost of rail transportation.

Since the construction, in 1875, of a pipe line from Oil City, Pennsylvania, to Pittsburgh to transport crude oil, the pipe-line system has spread out over most of the United States, but so unobtrusive and unspectacular has the growth of the system been that few are aware of the enormous, complex transportation network that lies beneath the surface of the country. Thousands pass over the lines every day without a thought for the millions of gallons of oil flowing beneath them.

THERE is not one of the 315,000 active oil wells in the United States that does not have an outlet for its production through a pipe line. When new oil fields have been opened up, pipe lines have always been prompt in providing the new areas with facilities for volume shipment, even in the most remote places. Soon after the discovery of

the East Texas field, the greatest source of oil yet uncovered, 17 trunk lines, capable of moving 1,000,000 barrels a day, were built to serve the new field. During the past year more than 1.215,000.000 barrels of crude oil, and 75,000,000 barrels of gasoline were moved in interstate transportation by the nation's pipe line system. So enormous is the system that it is estimated that more than 5,000,000 barrels of crude oil and gasoline could be moved in 24 hours.

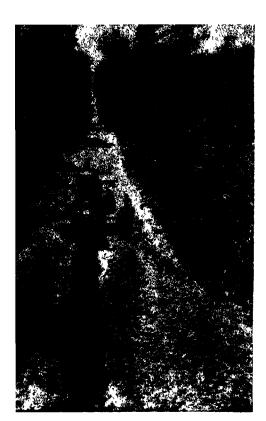

In planning the construction of a pipe line the first problem that must be solved is to find the route between the points to be connected that will permit the speediest and least expensive construction, and the most efficient operation after the pipe has been laid. Conditions of topography, drainage, and rights of way are all factors that must be considered, but the route must follow a comparatively straight line, for a route laid out to avoid all the difficulties of the terrain would probably be so circuitous as to make the cost prohibitive.

Acrial photographic surveying is a comparatively recent development that is proving an invaluable aid to the location engineer. The aerial photographic maps show the engineer all of the surface details in the horizontal plane, and with stereoscopic devices, similar in principle to the old-fashioned stereoscope that used to be standard home equipment, he can obtain a three-dimensional effect that shows all the details of elevation changes.

Such aerial surveys enable the engineer to plot a route across average country in his own office, with the assurance that few, if any, changes will be ne-

Pipe lines to carry oil and gasoline—many thousands of miles of them—spread like ap webs radiating out from the various oil fields to all parts of country. Here, one is being insta

ing machine anchored to a tractor and cuta trench for an oil pipe line on a steep slope

cessary when the route is staked out on the ground. In extremely rough country alternate routes can be plotted on the photographic map, with selection subject to a one-party ground check, whereas without the photographic map it would be necessary to put half a dozen surveying parties in the field to cover the possibilities of as many different routes.

In spite of all the study devoted to the selection of the best available route, nature frequently presents obstacles that test the skill and ingenuity of the construction engineers. A recently completed 225-mile line from Williamsport, Pennsylvania, to Rochester and Buffalo, New York, had to cross three riversthe Chemung, the Genesee, and the Susquelianna-and frequent swamp areas Precipitous, rocky hills and deep valleys, often heavily timbered, not only made difficult the transportation of pipe and other supplies, but placed tremendous strains on trucks, tractors, ditchers, and other machines

Even after trees had been felled, the stumps blasted out of the ground, and a roadway cleared by a machine known as a bull dozer, trucks were frequently unable to negotiate the steep slopes and the pipe had to be backstrung from the nearest accessible spot. The procedure was to weld the pipe into one continuous section and push it down the incline to the next relatively level spot where it could be welded to the section beginning at that point.

Many of the precipitous slopes even defeated the crawler-mounted machines capable of pulling 15 tons or more of deadweight up surprisingly steep grades. To help them up the slopes it was necessary to haul them with a wire cable from

a winch-equipped tractor anchored to a tree some distance up the hill. A machine used to back fill the ditches after the laying of the pipe, and admiringly referred to by the workers as "Popeye," somersaulted 15 feet through the air on one of the slopes, but was quickly repaired and returned to duty

Each of the river crossings presented its own problems. In the case of the Cheming crossing, which was not very wide or deep, a machine known as a trench hoe was mounted on two large timber runners and pulled across the river bottom by two winch-equipped tractors anchored on the far bank, digging a five-foot trench as it went. A barge fitted with an inclined runway was used to lay the pipe across the 1000 foot Susquehanna crossing. The lengths of pipe were welded together on the runway and allowed to settle into the river bottom ditch as the barge was winched across.

ALTHOUGH virtually every technique in the pipe line builder's manual had to be employed at one time or another to overcome the obstacles set up by nature, the crews employed on the job established some remarkable records for speed. On some of the less difficult stretches, as much as 25,000 feet of line was laid in a single day. The whole 225-mile line was completed in four months from the start of construction

In many respects, the operation of a pipe line is similar to the operation of a radroad, with its feeder or gathering lines, main trunk lines, terminals, storage yards, switch systems, stations, dispatchers, telephone, and teletype systems. Unlike the freight train, however, the pipe line does not have to move itself as well as its load. The fluid is kept moving through the pipes by pumping stations, usually located about 40 miles apart, although in hilly country, or for heavy and viscous oil, they may be placed at more frequent intervals along the route

Each station is equipped with pumps powerful enough to send the stream on to the next station, and is provided with storage tanks having a capacity ranging from 10,000 to 50,000 barrels Frequently three or four different "slugs" or batches, each consisting of from 25, 000 to 250,000 barrels, and each consigned to a different destination, will move in succession through the same pipe line Each "slug" may consist of a different grade of gasoline or other petroleum product. The inter communicating telephone or teletype system en ables the dispatchers to keep the station operators informed of the time when each batch will reach them, and to give the necessary instructions for shunting off the different consignments to the connecting lines that will carry them to their different destinations

No pick and shovel work is necessary after an oil pipe line is laid, a powerful bull-dozer tractor fills the pipe trench and cleans up the job in short order

VITAMINS FROM OUR OWN FISH

TODAY, because a young Minnesota pharmacist found experimenting with burbot an interesting diversion, Lake of the Woods fishermen are selling the once-despised fish for the valuable cargo of vitamins A and D they carry in their unusually large livers.

After graduating from the University of Minnesota school of pharmacy in 1929, Theodore Rowell settled in Baudette, Minnesota, near the Canadian border. When not working in his drug store, the young druggist was studying the burbot in his home-made laboratory. (The burbot is the only freshwater member of the cod family)

Soon after Rowell became interested in burbot and vitamins, an investigational report of the United States Bureau of Fisheries stated that, in experimental tickets, oil made from burbot livers was from three to four times as potent in vitamin D and from four to ten times as potent in vitamin A as good grades of cod-liver oil.

Working in his laboratory, Rowell learned that the liver of the fish made up 10 percent of its body weight and was proportionately about six times larger than livers of other northern freshwater fish. From 1931 to 1933 he worked on different methods of extracting the oil from the liver cells of the fish. After much experimentation he perfected a process that yielded amounts of oil equal to 40 to 60 percent of the liver's weight

Rowell's next step in producing freshwater vitamins was to evaluate burbot-liver oil as a vitamin-provider. Several litters of silver foxes served as "guinea pigs" for further experiments. For two years all foods containing any amounts of vitamins A and D were eliminated from the feeding chart and burbot-liver oil was substituted. The results were very gratifying.

EVEN better were the results of a study of the anti-rachitic factor in burbot-liver oil recently completed by Dr. Thomas Myers, instructor in pediatrics at the University of Minnesota. In order to test the anti-rachitic value of vitamin D as it occurs in burbot-liver oil, Dr. Myers selected 50 infants from one to two months old from a welfare clinic. Each was given a daily dose of ten drops of burbot oil. Dr. Myers found that, during the observation periods of six months to one year, the children made normal gains and developed satisfactorily in all cases. In no instance did any cases of definite clinical rockets develop.

A Local Druggist in a Minnesota Village Finds that there is Opportunity Outside the Crowded Cities and Develops an Industry Where He Lives

By E. J. FORTIER

His experiments had proved to Rowell that burbot-liver oil was six to eight times more potent than good grades of medicinal cod-liver oil. He also found that burbot oil has a very low viscosity and is more rapidly digested and assimilated than most fish-liver oils.

Early in 1935 the young druggist built a small factory near the shore of Lake of the Woods and launched in earnest the production of the new fish liver oil. Burbot-liver oil was introduced to the medical profession in September 1935,

A rather large burbot. Above it in a jar is a burbot liver proportionate to its size and, at the right in another container, the amount of oil that can be extracted from such a liver

Rowell in his home-made laboratory when hurbot provided only a hobby

and soon after was accepted by the council on pharmacy and chemistry of the American Medical Association.

Burbot are caught in the fall and early winter months when they come to shallow shore waters to spawn and feed. Each of 25 to 35 fishing crews on the Lake hires an extra man whose sole job is removing burbot livers. From 40,000 to 50,000 pounds of vitamin-providing fish are caught daily throughout the season.

The general steps in the Rowell process of manufacturing burbot-liver oil are, first, placing the livers in a large steam kettle in which high steam pressure breaks down the oil cells and frees the vitamin-laden fluid. Next, the oil is rendered and decanted and run into a cooling chamber which is kept at a low temperature until all the stearies have been precipitated and strained off. The oil, after being processed, is ready to be bottled and capsuled without being concentrated or blended.

The small factory on Lake of the Woods is the only place in the United States where burbot-liver oil is produced for commercial use. Moreover, the Rowell factory produces the only fish liver oil of which production is entirely controlled within the United States.

Fishermen are anxious to catch burbot for sale to Rowell not only to supply the new market but also because keeping down the burbot population will conserve game fish on which the ferocious burbot feed.

The amount of burbot available for production of vitamin-rich oil is inestimable. The fish are found in lakes and streams from New England and the Great Lakes region west to the upper Missouri and Columbia River basins, and north to the Arctic Ocean.

Burbot-liver oil has been discussed technically in an investigational report of the Bureau of Fisheries, Washington. D. C., also in *The Journal-Lancet*, Minneapolis, Minnesota

World's Biggest Meat Market

UCH of romance has been written about the famous million-acre King Ranch which spreads its broad tracts through southern Texas un til it touches the Gulf shore. Yet romance of the garish western plains variety has little place in this "World's Biggest Meat Market," which each year sends 15,000 to 20,000 head of fine cattle to beef-packing centers of the nation.

Rather, it is a story of patience combined with the ingenious application of scientific data and methods. These alone are responsible for the steady growth, improvement, and prosperity of this vast property. The facts comprise an interesting story—an imperishable tribute to the King and Kleberg men, keen-eyed and

The ranch house which is headquarters for the vast Texas domain that is the King Ranch

keen-minded rancher businessmen who in three generations established and developed the nation's greatest beef-cattle production unit. Robert J. Kleberg, Jr., president and general manager of the King Ranch, Inc. is a grandson of famed Captain Richard King who founded the enterprise in 1852 as the very first planned cattle ranch in the United States. All true cattle-ranching activity in this country grew from King's early work.

The property had and has nothing in common with the general agricultural expansion to the west Grain farmers spread out from the east, clearing and developing more and more new territory until they had opened a continuous farming country from the east coast to the

Famed King Ranch, America's First Planned As Such, Claims Title To Scientific "Firsts"... Its Organization Is Tribute To Man And Machine

By W. P. ELLIOTT

middle west, but the King Ranch is the result of no growth or westward movement; rather, it was deliberately selected out of the middle of a semi-tropical wilderness, isolated from city and village.

The original purchase consisted of 69,000 acres now known as the Santa Gertrudis division of the ranch, Captain King was aided in his first selection of

land by his friend, General Robert E. Lee. Much of the original purchase was in the natural sod of the torud coastal plains and, even then, stubborn mesquite growth had begun its inroads

Of course, modern transportation and refrigeration were unknown, so only non-perishable commodities such as tallow and hides could be produced. At Captain King's death, the late Robert J. Kleberg, Sr., who had married the original owner's

daughter, became general manager. More land was acquired, although the owners knew that this was not the real answer to the irksome problems which already had begun to manifest themselves. Heavy losses were being suffered because of the deadly fever ticks, screw worms, and many other parasites which externally and internally attacked the great herds of cattle. These were added hazards for, first of all, the range cattle were far out of their climate element. They couldn't stand the extreme heat

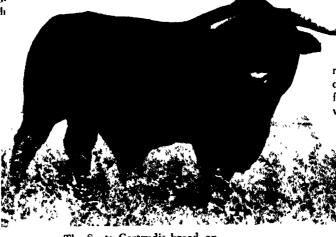

THUS, several decades ago, King Ranch owners summarized their problems and their goal as: 1, To provide dependable supplies of water; 2, To secure adequate transportation to big markets; 3, To eradicate fever-bearing ticks, 4, To develop a breed of cattle able to withstand heat and disease; 5, Land improvement through eliminating standing and running mesquite which threatened the entire ranch, and establishment of a range grass which would thrive despite drought and provide nourishment adequate to carry cattle and bring them to a

marketable weight in short

To reach this goal meant much scientific study. The King Ranch then began itremarkable series of "firsts" by dipping cattle to eradicate the fever tick, Abundant supplies of water were secured through the

initiative of Robert J. Kleberg, Sr., in drilling the first artesian well in South Texas, discovering underground water stocks on which hinged much of the later ranch and farm development of the area. There still, however, was no answer to the heat problem. Many sheds were built to shelter the stock from the broiling sun, but cost and enormity of the project made the method prohibitive.

Then from far-off India came the answer—the Brah-

The Santa Gertrudis breed, an important scientific contribution to cattle raising: first breed developed in America

A simple yet important innovation: smooth wire fencing instead of burbed wire which often slashes range cattle badly

ma bull. Brought to the ranch 18 years ago was a gift bull sired by a Brahma out of a shorthorn cow. This was the foresire of the famous "Santa Gertrudis" breed of cattle. The ranch had begun, long before, to cross-breed shorthorn and Hereford bulls with common range cattle, finally breeding them pure. The cattle were good for feed lots-for someone else to feed and mature-but they had lost their hardiness, their resistance to insect pests and their ability to fatten. The cross-bred Brahma bull, upon its arrival at the ranch, was pastured with 3000 unregistered, pure-bred shorthorn cows, along with other shorthorn bulls. From all the calves therefrom, 60 of the best females and one bull calf were selected as the finest beef calves in the range's history.

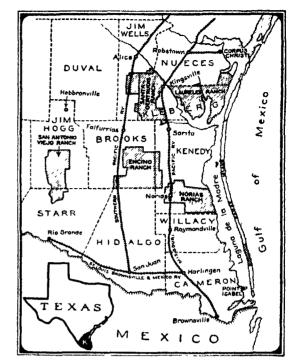

Fifty-two Brahma bulls were immediately purchased and the process of selection, line breeding, and inbreeding was scientifically continued. A great sire was developed, and at length, the famous bull, "Santa Gertrudis," was bred, representing near perfection. This great bull is head of the King Ranch herd now.

Today, steers of the ranch calf crops average from 100 to 200 pounds heavier at one year of age than Hereford and Durham cattle and are carried to marketable weight in the shortest length of time. They withstand drought well. The obstacles of heat and disease have been decisively licked. The ranch gets credit for one of the most progressive steps in American animal breeding history—a veritable milestone in the cattle industry. It was another "first" for the Klebergs.

The Missouri-Pacific railroad, in 1900. had solved the major transportation problem, so that only one remained—more and better pasture for the rapidly

growing herds. In the closing years of his life as a great builder Robert J. Kleberg, Sr., often said that. if he had his work to do over, he would improve the land he owned rather than purchase more and more land for expanding herds. The demon mesquite annually was taking more toll of valuable grazing land. At first, Mexican hand labor was used in an attempt to clear the land. The original owner had given employment to all who came seeking it, but the results were costly and the progress was

In spite of cost and bad times, the ranch management continued to use hand labor, although clearing represented six man days per acre! To feed and employ men liberally was all well and good but it was not getting the job done that

The several large ranches comprising the King Ranch holdings. Note section on the island. Inset map of Texas shows (K) general location

The "tree-dozer" showing, in small picture, the pusher bar and the heavier cutting edge beneath it. Below: The machine rips into large growth with no great effort

had to be done. Young Bob Kleberg then tried wheel tractors equipped with winches to yank out the stubborn mesquite, but with little success. So he put his head in his hands, sharpened up his pencil, and did some serious and scientific thinking, possibly remembering that his father long before had visualized a steam plow in the realization that successful clearing operation would require a machine that could move right along in continuous operation. He sketched a great pushing, ripping, cutting tool which would

literally tear the heart out of the mesquite jungle, leaving it clear for the planting of palatable grass food for his herds. What power, however, could pull or push such an implement? The job required not only power but traction—something that could crash through the tangle, push over trunks two feet in diameter, disregarding uneven or soft footing.

The rancher then thought of the tracktype tractor and decided the most powerful model might do the trick. He called upon the distributor at San Antonio who handled "Caterpillar" Diesel track-type tractors This company and allied manufacturers studied Kleberg's description and sketches and devised what came to be known as the "tree-dozer."

This implement, mounted on the front end of a 95-horsepower Diesel tractor, consists of two independent parts. One is a pusher bar carried ahead of the tractor's nose, arranged so that it will strike the tough mesquite trunk from 1½ to 7 feet above the ground. The other

part, just below the pusher, resembles a bull-dozer. Three feet high with a heavy, keen cutting edge, the bull-dozer adds the "two" to the "one-two" punch delivered by the unit. Both parts are sturdily mounted and either hydraulically or cable driven by the tractor operator.

In operation, the tractor plunges into heavy mesquite. The pusher bar strikes

power—pulling power—the ingenious rancher concluded, and he proceeded to devise another tool, a heavy ten-foot blade to be drawn eight to ten inches under the ground and parallel to the surface, the blade to be supported by uprights fixed to a heavy bed. Again the tractor distributor and allied equipment makers aided, and the "knife rooter" was born. The implement required plenty of

The "knife rooter": a powerful tractor draws a heavy ten-foot blade several inches under the surface of the soil to cut off the roots of, and destroy running mesquite

the trunks first, bending them forward and exposing the roots. The cutting edge below "follows through," striking at the roots of the bent mesquite and quickly gouging out the growth.

How effective this unit is can best be told by the following data:-The first Diesel track-type tractor and tree-dozer delivered to the ranch has worked 6700 hours and has cleared considerably more than 10,000 acres of hitherto mesquitetangled land of low economic value which now is seeded in nourishing, hardy Rhodes grass. It is thought that approximately 80 percent of this clearing is permanent or results in 80 percent destruction of brush growth. Use of the treedozer is expected to cheapen costs of clearing but it is early to place an exact cost figure because of varying local conditions and size of jobs. The cost of operating the tree-dozer alone on the King Ranch jobs, including low-priced Diesel fuel, lubricating oil, operator's wages, and depreciation has amounted to only approximately \$1 40 an acre.

STANDING mesquite, however, is only half the problem. During the last few years, there has been a rapid encroachment of "running" mesquite onto what had been good pasture land. Of small diameter, this energetic native brush of the Texas gulf coast reaches a height of from six inches to four feet. Its tough root system masses to choke out the grass, and the brush often contains more growth underground than above.

Here was a job that also called for

power and again the 95-horsepower Diesel track-type tractor was called upon to pull the tool.

Success again smiled. The outfit was able to destroy two acres of running mesquite an hour. This rooter equipment, used in conjunction with the tree-dozer, results in complete destruction of all brush. The ranch let this job to a contractor who will clear 25,000 acres per year for the next four years. The ranch will continue to clear land with the tree-dozer and seed it to five pounds of homegrown Rhodes grass seed per acre.

And so the last of the King Ranch's major problems was solved. There are other "firsts" to the credit of the ranch, and it may be well to list some of them, for they have contributed immeasurably to southwest ranching: First cattle ranch in the United States. First ranch to kill fever ticks by dipping cattle. First and only ranch in the United States to develop and bring to perfection a distinct breed of cattle. First ranch to provide a range grass that would withstand heat and drought. First to abandon the use of barbed wire and to substitute smooth wire fastened to posts without the use of staples. First to invent the humane and efficient electric prod for handling cattle. First to develop and use the treedozer and knife rooter to clear mesquite ridden land.

Kleberg, Jr., has made no secret of his experiments and the results are available to ranchers throughout the world.

Fellow ranchers along the Rio Grande valley are already adopting his landclearing methods and following his advice in stockbreeding, care and feeding. They are warm in his praise, declaring that he has done more than any other individual to advance cattle ranching, and all in the face of great odds.

King Ranch, Inc., at present consists of five divisions, each under direction of a superintendent and totalling approximately 900,000 acres over which graze 50,000 head of beef cattle. These divisions employ approximately 450 Mexican laborers. Headquarters, where the beautiful ranch house is located, is Santa Gertrudis. On this tract a purebred Jersey herd supplies milk free to employees of this division and to former employees now living on pension in nearby Kingsville.

SUCCESS of the large enterprise is attributed freely to the co-operative work of the management personnel which acts as a smoothworking team. Each man is responsible for certain definite work but each also brings his contribution to the solution of any problem that may arise Chairman of the board is Richard M Kleberg who represents his district in the Congress of the United States. Robert J. Kleberg, Jr., is president and general manager. Caesar Kleberg is assistant ranch manager. Alice G. K. Kleberg is secretary and treasurer and A. L. Kleberg is office manager and secretary. Tom East is head of the sales department General superintendent of farming is Worth Wright and ranch division superintendents are Charles Burwell at Laureles, Lauro Cavazos at Santa Gertrudis, Jim McBride at Encino, Tom Tate at Norias, and Tom East, Jr., at San Antonio Viejo.

Important job of chief veterinarian is held by Dr. J. K. Northway who is in charge of the dairy herd and who supervises medical care and breeding of all herds. The ranch raises its own horses, and every horse used by the ranch cowboys is an offspring of the Mexican quarter horse and the English thoroughbred.

Selective breeding is all done on the headquarters division. Breeding cows and bulls raised there are supplied to the other four divisions. At present there are approximately 40,000 breeding cows with one bull to each 50 cows.

Small wonder the beginnings of this magnificent property have received more than their share of romantic writing. It would seem, however, that there is more romance in the struggle for existence and financial success—in overcoming with science and ingenuity those obstacles, any one of which could have meant oblivion to the clan of King-Kleberg as great ranchers.

To this belief the many thousands of sleek, dark red cattle with those strange humps reminding one of the Orient, grazing in many herds and disdaining the blazing sun, give eloquent testimony.

Problems

Are Scientific American Readers Interested in Mathematical Problems? To Settle this Debated Ouestion The Editors Offer These as a Test

By LEONARD KAPLAN
Lieutenant Commander (CC) United States Navy

To the average human being a problem, like an unsolved puzzle, stands as a challenge. "Ha! you can't solve me," the problem seems to jeer, while the human being replies: "Are you positive? And just to show you how very mistaken you are, I am also going to solve you—and now." And solve it he does—well, maybe!

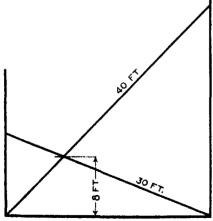

The five problems on the present page are offered by one of the United States Navy's builders of battleships whose recreation in off hours is this kind of sport. No prize is offered for their solution; they are presented merely because many readers like to tussle with something a bit tough. The answers, but not the solutions, are given on page 251. Of the two, the solutions are of course the principal factor, though for lack of space these cannot be published--some of them are rather lengthy. However, in case of heavy interest in any one of them the question of publication of the full details of solution will be reconsidered.

Whether you find these particular

problems dead easy, plain easy, average, a bit difficult, or very hard, will naturally be a matter of relativity: that is, whether you happen to be a mathematician, a mathematician of sorts, or are a creaky mathematician (many a former good mathematician, alas, has found that, when not actively need for a few years, his once bright and shining classroom schooling in mathematics apparently has oxidized a bit). However, the tougher the problem the more satisfaction in cracking it. The "Problem of the Crossed Ladders" will require algebra, the "Problem of the Spheres" can also be solved by algebra, the "Problem of the Barge on a Rock" requires "trig," and both of the "Dog and Rabbit Problems" will necessitate use of the calculus.

Problem addicts are requested to address their entire problem correspondence direct to the author, in care of this magazine, but kindly not to the editors who, with a magazine to get out each month, have pressing problems of their own—The Editors

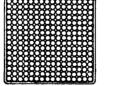

The Problem of the Crossed Ladders: Two ladders, one 30 feet long and the other 40 feet long, rise to oppo-

site sides of an alley lined by vertical walls, and intersect (in projection) at a point eight feet above the ground, as shown in the drawing. How wide is the alley?

The Problem of the Spheres: A

receptacle infinitely large is filled with spherical balls one inch in diameter. What proportion of the space within the receptacle will be occupied by the

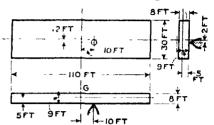

balls and how much will be void, assuming that the balls are stowed as compactly as possible [shaken down.—Ed.]? What will be the proportions if half-inch spheres are substituted, as shown?

The Problem of the Barge on a

Rock: A barge of rectangular section throughout, having the following dimensions: length 110 feet, beam 30 feet, depth eight feet, is floating on an even keel at a draft of five feet, with the center of gravity nine feet above the

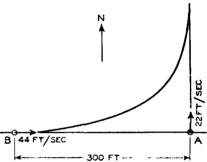

base. The barge touches upon a rock ten feet forward of the middle length and two feet outboard of the center line. The tide then falls six inches. Find the drafts at the four corners of the barge and the

pressure upon the rock in this condition. (Assume salt water 35 cubic feet per 2240-pound ton.)

The Dog and the Rabbit Problem:

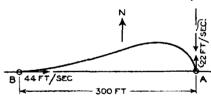

A rabbit runs northward from a point A at a rate of 22 feet per second. A dog, starting from a point B, 300 feet west of A, at the same time, runs on an ever-

changing course directly toward the rabbit, at a rate of 44 feet per second. How long will it take the dog to catch the rabbit? How many seconds after starting will the dog be headed northeast?

Second Dog and Rabbit Problem:

A rabbit runs northward from a point A at a rate of 22 feet per second. A dog, starting at the same time, from a point B, 300 feet west of A, runs directly to-

ward the rabbit at a rate of 44 feet per second. Assume now that the rabbit, after having run some distance north. sees the dog, reverses his course suddenly and runs south at the same rate of 22 feet per second, the dog meanwhile continuing to run at a rate of 44 feet per second directly toward the rabbit. How many seconds will have elapsed from the starting time to the time when the rabbit changes course, if both the dog and the rabbit are to arrive simultaneously at the original starting point A? In what direction will the dog be headed at the moment the rabbit reverses his course?

(Answers on page 251)

Berenice's Hair

N a clear spring evening, when the Pointers have passed the meridian, and the middle of the Dipper is high above the Pole-Star, one may see, high up, and south of the zenith, a cluster of faint stars. Individually, these are far from conspicuous; but there are enough of them to catch the eye if the night is dark. Moonlight drowns them out almost completely.

Star gazers seem to have had an eye for such groupings, even though faint, for this insignificant group has had a name of its own and been recognized as a constellation since classical antiquity. It is known as Coma Berenices—Berenice's Hair Alone among the ancient constellations, it commemorates a historic individual—Queen of Egypt in the 3rd Century B. C.—yet the name was generally adopted, and Catullus, 2000 years ago, wrote a mock-heroic poem in honor of this parvenu in the celestial spaces—probably itself a translation from an older Greek original.

The astronomer of the present day has a human, but not a professional, interest in these ancient tales; but the constellation itself has plenty to interest him. Like every other, it contains stars of individual interest—double, variable, and the like; but its appearance naturally arouses the inquiry: Is this a mere accidental conglomeration of unrelated stars, some of them far more remote than others, or a real cluster of objects at about the same distance, and of common motion and origin; or have we a real cluster, mixed up with other stars, in front of it and behind?

From what we know in other cases, the last would be the best guess. A number of star-groups, most of them recognized and named from antiquity, are now known to contain stars which are really related to one another-the Pleiades, the Hyades in the head of Taurus, Orion, the Great Bear (our modern Dipper), Scorpio, and the Southern Cross. But in all of these except the first, some of the most prominent stars belong to the foreground or background, and not to the true cluster. There are, however, other groups, almost as promising in appearance, which prove to be mere chance collocations—such as the pretty semicircle of Corona Borealis, or the great cross of Cygnus.

To distinguish one of these situations from the other, and to pick out the real cluster-stars from the interlopers, is sometimes casy. The naked-eye stars of the Pleiades, for example, are appar-

Recent Research Proves That This Nearby Cluster of Stars Is No Mere Accidental Conglomeration of Unrelated Bodies but Is an Interrelated System

By HENRY NORRIS RUSSELL, Ph.D.

Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Mount Wilson Observatory of the Carnegie Institution of Washington

ently moving in the heavens in very nearly the same direction, and at almost the same rate, so that there is no more reason to doubt their real connection than in the case of a flock of birds flying together across the sky. The same is true of many, though not all, the stars of the Hyades. Aldebaran, the brightest of all, is moving faster and in quite a different direction, so that it clearly does not belong to the group.

We can thus pick out, and omit from our counts, many of the aliens; but, though this test often affords a conclusive ground for exclusion, it is obviously not a perfectly safe test for admission. Among the many stars in the large region of the sky covered, for example, by the Hyades, there are likely to be a few whose proper-motions, by mere chance. happen to agree closely with that of a cluster star. Even when allowance is made, as is necessary in this instance, for the perspective effect of apparent convergence of the really parallel motions of the cluster-stars, a chance coincidence is still possible

TO weed out these strangers, we may have recourse to the radial velocities. spectroscopically determined The real cluster stars must be moving togetherthis is, indeed, the physical definition of the cluster. Hence they will all be approaching us (or receding from us) at the same speed (apart from perspective effects in a very widely scattered group). The great majority of the stars which show substantially the same proper-motion should therefore have the same radial velocity. Those which disagree by more than a reasonable allowance for the small errors of measurement must again he rejected—they have passed the first selecting screen, but not the second We must be a bit careful here, for a star may be a spectroscopic binary, with orbital motion of its own. Repeated observations will show changes in the velocity as it moves around its orbit; and, if they are kept up, will make it possible to calculate and allow for the orbital motion-when

the original test is applicable to the remaining motion

There is still a third test. The stars of a real cluster can not differ greatly in distance from us -unless, indeed, the cluster itself happened to be an elongated cigar-shaped affair pointed directly at us, which is too improbable to bother about. For such practically equidistant objects, the differences in apparent brightness will reproduce those in real brightness-if one star is ten times as bright as another, it will look ten times as bright. When the apparent brightness (stellar magnitude) of the cluster members is plotted against the spectral types. a diagram of the familiar sort is obtained. Ordinarily, the bulk of the stars belong to the "main sequence" in which the redder stars of "later" spectral type are increasingly fainter, the redder they are. There are sometimes, though not always, a few bright red stars which really belong to the cluster, and are "giants" Ostensible cluster-members which fall outside these two classes are suspicious. Those which pass the proper-motion test. but fail here, usually fail also when the radial-velocity test is applied, and do not belong in the list at all. The chance that a star would, by sheer luck, get by all three of these tests is small enough to give us little concern (unless, indeed, we have thousands of probable cluster members to deal with-which has not yet happened).

This last test has another value. There are several clusters for which the distances of the stars may be found, reliably, but in ways of which there is no space here to speak. In these cases the real brightness of the stars can be found from their apparent brightness; and it then appears that the real brightness of a main-sequence star of the same spectral type (say G0, like the Sun) is closely the same in all the clusters—and also among the individual stars, nearer the Sun, for which we have good parallaxes. This means that stars similar in spectrum are at least pretty closely similar in brightness, and presumably in other properties.

If the same is true in other clusters, we can find their distances by comparing the apparent brightness of stars belonging to them with the real brightness corresponding to their spectral types. It is, of course, necessary to be sure that we are dealing with main-sequence stars, and not with the far brighter giants; but the diagrams already described make it clear that this can almost always be safely done.

A detailed, careful, and very convincing study of the cluster in Coma Berenices has recently been made by Dr. Trumpler of the Lick Observatory, who has already investigated many other clusters. Though known from antiquity, this cluster presents a peculiarly difficult problem. Its stars are fairly bright, but their proper motions are small, and in the direction of the general apparent drift produced by the Sun's motion in space. The unrelated stars are more likely to show apparent motions of this sort than of any other. Hence, though many of them will be rejected by the proper-motion test, the number which get by will be larger than for other clusters, and a list based on this test alone will contain non-members. The radial velocity, too, is small, and near the average for all the stars, but this test suffices to reject the majority of the stars which have sneaked into the first list. When the third test is made, by plotting the apparent magnitude against the spectral type, a few cases where both the other tests must have been passed by chance are revealed; and the remaining, thrace-tested list, should be trustworthy.

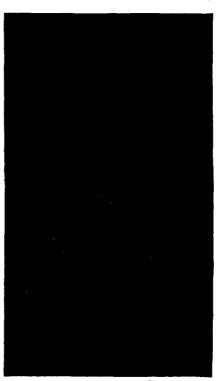

To secure this result, all three tests have to be worked for all they are worth—and the account of the way in which this was done fills most of Dr. Trumpler's 28 large pages.

There is plenty of material for the proper motions, but the various sets of observations by nine different observers had to be most carefully compared. The minute systematic differences which are always to be found between the results of even the best work with different instruments and methods were carefully determined and allowed for, till, at last, a homogeneous set of results was obtained, representing the final result of more than a century of observations with the meridian circle, and 60 years' photographic work.

When these motions were plotted, those of a dozen or more of the brighter stars were so nearly identical as to make it certain that a moving cluster really existed. The fainter stars showed a group with this same motion, but more doubtful cases—as well as still more to be excluded.

The radial velocity test came next. Twenty-one stars had already been observed, at various places; 47 more were added by special observations at the Lick. Most of these stars are faint, and a great deal of work had to be done to get the three spectra per star which are needed to weed out variable velocities and get good average values.

To get uniform material for the third test, the photographic magnitudes of many of the stars were determined by new observations, and the results of earlier observers were re-discussed and combined with these. Most of the spectra were already given in the great Henry

The constellation Coma Berenices, photographed by Edward E. Barnard at the Yerkes Observatory.

In his text Professor Russell mentions the origin of this odd name for the tiny constellation. In more detail the story is that Berenice was the wife of Ptolemy Euergetes, of Egypt, who reigned about 250 B.C. She was a blonde and she vowed that if her king, who had gone over to Babylon to fight a war, came back victorious, she would cut off her tresses of amber and place them in the temple of Venus at Zephyrium. The Ptolemy won his battle and the lady really made good her promise, but somebody stole the hair from the temple! The Astronomer Royal, a diplomatic man, thereupon jumped into the breach and named this cluster of stars Berenice's Hair. so Berenice had hair again

Draper Catalogue, but 18 faint stars were specially observed at Harvard to make the list as complete as practicable.

When all this mass of work had been done, it was at last-possible to apply the three tests with the new, homogeneous data, and be sure of the significance of the results.

Out of an original working list of 212 stars, and an additional one of 21 fainter

objects deserving investigation, 37 stars passed all three tests—leaving no doubt that a physical system of stars with common motion is really present. Seven fainter stars, for which radial velocities were not easily to be observed, pass the other two tests, and probably belong to the cluster. They are widely scattered over the sky, in a circle 7 degrees in diameter—making this one of the largest of all clusters as regards apparent size.

The brightest cluster star is of magnitude 4.8, and there are five others brighter than the sixth magnitude. Five other stars, in the same region, and above the same limiting brightness, have nothing to do with the cluster.

The proper-motion of the cluster is small, 0°.021 per year. Its parallax, determined by comparison of the real and apparent brightness of the cluster stars. is 0°.013, making the distance 75 parsecs, or 250 light-years. The real motion in space is in almost the same direction as the Sun's and at two thirds the velocity, so that the Sun overtakes it at the unusually small speed of 7.5 kilometers per second. The outer diameter of the cluster is about 30 light-years. The brightest star in the cluster is 50 times as bright as the Sun. The faintest which have so far been identified has about 1/30 the Sun's brightness. All the stars but two belong to the main sequence, and have spectra ranging from A0 to K2 The rate of decrease of brightness with increasing redness is very similar to the average for other clusters. The two giants are of unusually early types, A8 and F4.

The cluster is a "poor" one, containing less than 50 stars; but this is nothing remarkable, for nearly half the more distant galactic clusters which have been recorded in Trumpler's work are no richer. In its central part, stars brighter than one fifth the Sun's light are, however, more than 50 times as thickly strewn in space than in the general field outside, so that it is a very real affair. Indeed, calculation shows that the mutual attraction of its members should suffice to keep them together-though by no very wide margin. Compared with a rich cluster like the Pleiades, Coma Berenices shows a smaller proportion of faint stars. Whether this is true of other poor galactic clusters we do not know—they are too far off.

TWO incidental characteristics may be mentioned. This is one of the nearest clusters—only the Hyades and the Ursa Major group being nearer; and, as we see it, it is about as far as possible from being "galactic," since it lies within a few degrees of the north pole of the Milky Way. Its distance, in space, from the galactic plane is not abnormal. We are so close to it because we are—so to speak—right under it, which accounts for its apparently unusual position.—Princeton University Observatory, February 5, 1939.

INSECTS CANNOT WIN

T seems to be the general impression that insects are more numerous and troublesome today than they were during our youth. Is this true? Yes, and no. Some insects are more numerous and troublesome. For example: grasshoppers, which were long but a legend to us-a legend of the pioneer days in the Dakotas, Nebraska, and Kansas, those days when the sod-hut settler was driven from his claim by the vast hordes of Rocky Mountain locusts that swept into his fields and left no single green thing. It is also true that many new pests have come into prominence during the present generation. We have seen the coming of the European corn borer, the Japanese beetle, and the white-fringed beetle, the last so new that it is not known to the general public but is only too well known to the farmers in a small area in northern Florida and southern Alabama.

IT is not true, however, that most of our insect pests are remarkably more numerous than they were during the last generation. They are merely attracting more attention. The last generation accepted worms in apples as a normal state of affairs, and gouges in the side of potato tubers occasioned by white grubs and wireworms were expected The early canning industry and the consuming public paid little heed to fragments of insects in canned goods. They could not be seen and were, therefore, "not present." Today we have a very discriminating public. An apple pack must be absolutely free of insects, and the canner is very carefully watched by health authorities to see that no insect fragments, even though discernible only with a microscope, shall be in the can that reaches the consumer. What was considered a very satisfactory crop a half century ago is nearly crop failure today, with exactly the same amount of insect damage. The rôle of insects as factors in human diseases and diseases of livestock has attracted very considerable attention. Even many plant diseases are carried by insects. Our public has also been made very insect-conscious by the press, the radio, and the motion pictures. The layman knows that insects can be controlled and therefore insists that they must be controlled.

Will insects eventually destroy man? Not without some vast change in this earth on which we live. Quite true, they are capable of multiplying at a rate that is astounding. The progeny of a single pair of aphids, if they all lived, reproduced, and their offspring lived for one

Civilization's Unnatural Balance Cause of Apparent Victory . . . Most Insects Are No More Numerous, Only More Notorious . . . Many New Insecticides

entire year, would fill up the Atlantic Ocean with their bodies. But this does not occur. Nature is a beautifully balanced machine; not static, but slowly progressing, first with one group being dominant, then another. The giant reptiles had their day millions of years ago. Then the changing earth gave the mammals an inning in the Tertiary period. But during this time, and long before, the insects were maintaining themselves in very similar conditions and even in very similar form to the insects of today.

In the primitive jungles of the tropics insects occur in countless numbers and

kinds, but vegetation and primitive man live with them. That is the keynote of the whole situation. Primitive man, primitive conditions, all nicely balanced; but civilized man promptly destroys that balance. He introduces the plow. He cultivates large areas of exotic plants. He brings in livestock. New adjustments must necessarily take place These adjustments, however, take thousands, even millions, of years and man cannot wait. In order to maintain this unbalanced situation that he must maintain with his present civilization, he must strike

an artificial balance and he does this by, in one way or another, making his cultivated fields and domestic animals an unsuitable environment for the insects.

Probably one of the greatest advances in the control of insects was the discovery that arsenic, then in the form of Paris green, was very poisonous to insects. New arsenicals were discovered in rapid succession. The boll weevil that crept across the Rio Grande late in the 19th Century threatened to wipe out an entire civilization built up around the production of cotton in our southern states. This insect is adequately controlled by dusting with

A healthy (though not very luxuriant) field of corn before it was attacked by grasshoppers. A fair crop might have been expected from it

The same field as that shown above, after grasshoppers had feasted on everything but the hard-skinned stalks. Such grim reminders of the appetites of hordes of insects have caused apprehension, in the minds of many, as to man's ability to defeat the insects

calcium arsenate. But, to illustrate how easy it is to upset the normal balance, the application of this calcium arsenate, in addition to destroying the boll weevil, destroys a number of insects that feed on the cotton aphid; and often the application of boll weevil control methods is promptly followed by serious outbreaks of the cotton aphid.

The last half century can almost be called a chemical age. The science of chemistry has advanced so rapidly that there is hardly an activity of man that today is not stimulated and in some cases made possible by the work of the chemist. This great development of chemistry has

also vastly improved our methods of attacking insects, and today large numbers of highly trained chemists are working in the Federal Government laboratories at State experiment stations, in private insecticide companies, and individually on the improvement of munitions of war used in our battle with the insects.

Of course many insects do not lend themselves to control with chemicals and many of our most successful methods of combating these pests have been along quite different avenues of attack We control the hessian fly with our knowledge that this insect emerges at a very definite time with relation to climatic conditions. With this knowledge, we plant our wheat after the flies have emerged and died. We know that certain bark beetles-those pests which destroy more timber in any year than do the dreaded forest fires and which, in addition, are the predisposing cause of many of these fires because the insect-attacked forest with its tangle of fallen trees is a very potent factor in these great conflagrations—can be controlled, if discovered in their early stages, by simply felling infested trees and removing the bark or otherwise destroying the brood of bark beetles.

Another very important line of attack is our attempt to re-establish the balance in Nature's battle. This method is particularly applicable to insects brought to this country from foreign lands.

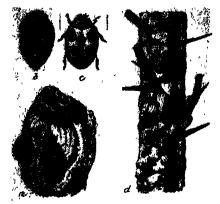

In the land of their origin, these insects have an established balance. They are preyed upon by other insects, they are attacked by disease; they are fed upon by birds and mammals, and do not multiply in the devastating hordes that they do when they reach the land of the free—free of all their enemies and diseases. By studying these insects on their native heath, we discover these natural enemies and introduce them into our own land. Early in the citrus industry of California, the cottony cushion scale

natural enemies and introduce them into our own land. Early in the citrus industry of California, the cottony cushion scale was introduced from Australia and grew "bigger and better" in the land of perpetual sunshine. An entomologist was sent to Australia to look into this matter. He found a little lady-beetle, the Vedalia, and brought it to America, the cottony cushion scale is no longer a pest in the citrus groves of California.

HERE, however, we will direct our attention to the control of insects with insecticides. This is no simple matter. It is not merely the discovery of a poison that will kill insects and then its application to all insects. That there are now estimated to be 624,300 different insects in the world, that in our own country we have records of over 20,000 different kinds of insects that are of some economic importance and over 6000 of these are actual pests, is not generally known. These insects have a great diversity of form and habit. They can live under almost any conditions found in Nature. Insects live in crude petroleum wells; they live in saturated salt solutions; they live in springs hot almost to the boiling point; they live on the most barren deserts; they live long periods of their lives under water. They feed in many different ways; they breathe in many different ways; they reproduce their kind in many different ways. All of these diversities require differences in treatment. A young mosquito lives in water, and any attempt to kill mosquitoes that are flying about the house is almost wasted effort. These insects, while in the water, breathe through a tube in the tail that is thrust above the surface. Hence an approved method of control is to separate this tube from the air by placing a film of oil on the water.

Plant lice, the chinch bug, all our scale insects, cannot be poisoned by placing poison on their food, as they do not feed that way. These insects have their mouth parts developed into a sucking tube which they thrust through the poison and into the unpoisoned plant tissue beneath. These must be killed with an insecticide that will destroy them by coming in contact with their bodies, or by a gas that will enter their bodies by other methods than through the digestive tract. Some insects are attracted to certain substances. These insects can be killed with poisoned baits. Others are repelled by certain substances, and crops are protected by applying these repellents. Each insect, by its peculiar habits, requires either a modification in the insecticide used or in its method of application.

Another factor that further complicates the problem is the changing standards of human welfare. For many years, arsenicals were standard insecticides. Then it was discovered that quantities of these poisons, believed to be detrimental to health, were being consumed on foodstuffs that had been treated with these insecticides, and prohibitive legislation against such foods made it necessary for the entomologist to start his attack anew. Certain other insecticides were not compatible with fungicides that were being used on the same plant for the control of the fungous diseases, and modifications or new insecticides were found necessary. The early work was largely with the inorganic chemicals as base materials in developing insecticides. We are now rap-

idly moving into the field of organic chemistry in insecticide work.

Organic insecticides are showing great promise. Most of these substances are obtained from plants, some from cultivated crops, others from forest products, and still others from weeds. Those in another group are built up in the chemical laboratory and are known as synthetic products. Every year, the waste material of the tobacco industry is used to produce about a million pounds of nicotine, which is equivalent to about $2\frac{1}{2}$ million pounds of the commonly used solution sold as nicotine sulfate. This material is one of our most valuable insecticides, having

fish so paralyzed were not in any way poisonous when eaten. The active principle of derris is rotenone, one of the most powerful insecticides yet discovered. It is 30 times more poisonous than lead arsenate to the larvae of the silkworm and when used on aphids it is 15 times as toxic as nicotine. It is so poisonous that one part in 13 million parts of water will kill goldfish, and yet is but slightly, if at all, poisonous to mammals-being only 1/100 as poisonous as lead arsenate to rats. This material is almost an ideal insecticide. It is not injurious to plants or animals sprayed or dusted with it. It does not leave on foodstuffs a residue that is poisonous to man or domestic animals, and it can be applied in doses small enough to be economical. In 1937, over 570,000 pounds of derris were imported into the United States from British Malay, the Dutch East Indies, and the Philippines.

In addition to derris, other plants contain rotenone. Of these, devil's shoestring occurs as a common weed throughout the United States—a plant belonging to the bean family which occurs on land so poor that little else will grow. Research work on the production of devil's shoestring having high rotenone content is now under way. This research may lead to our being self-sufficient in the production of rotenone. A third source of rotenone is a root from Peru and Brazil known as lonchocarpus. Last year we imported over a million and a half pounds of this root for use in compounding insecticides

Oils obtained from corn, cotton, soybeans, linseed, peanuts, and many other plants have been found to have decided insecticidal value. Certain of these oils are more toxic to mealybugs than are the usual petroleum oils used for this purpose. They have a decided advantage over petroleum oils in that they are better solvents for such insecticides as rotenone. It has been found that the addition of soybean oil to nicotine bentonite increases the toxicity of nicotine on apples and thus insures better control of the codling moth. It has also been found that the addition of certain of these vegetable oils increases the toxicity of certain other organic poisons such as derris, nicotine sulfate, and anabasine sulfate

Soaps made from corn oil, cottonseed oil, soybean oil, and other organic oils, possess high insecticidal value. It has been found that the fatty acids derived from plant oils may be used in place of acetic acid in Paris green and the resulting compounds have greater insecticidal value and are less likely to damage plant tissue than ordinary Paris green.

The future of insecticide development is very promising An acid from the cocoanut is the base of a potent insecticide. Oat hulls and corn cobs yield furfural, and derivatives of this remarkable compound have given promising results Sulfur, when combined with other substances found in plant oils, has been found to be quite toxic. Corn, rye, wheat, and other agricultural surpluses may be fermented to produce alcohols which, by proper combination, produce substances of great insecticidal and fungicidal value The day may come when insecticides made from wastes and very cheap products will so reduce the price of insecti cides that that margin on which the farmer lives, often so narrow, will broaden out and lead to a better farm life and, in turn, by reducing the cost of agricultural products, to a better national life.

long been known as a fumigant and as a contact insecticide to kill such insects as aphids.

Recent research work has demonstrated that a combination of nicotine with a clay-like substance known as bentonite forms a very effective stomach poison which promises to become a successful substitute for arsenate of lead in the control of the codling moth.

In 1937, nearly 20 million pounds of pyrethrum flowers were shipped into the United States, the great bulk of the material coming from Japan, sizable shipments also being imported from Jugoslavia, Kenya Colony, and Brazil. An insecticide is prepared from these flowers which is the base of many of our most useful fly sprays.

The natives of the East Indies and Malaya have long known that the roots of a plant called derris, when pounded up in water, would paralyze fish and that

World's Safest Ships

Sea Disasters Too Frequent in Recent Years . . . American Ship Lines Attack the Problem . . . New Ships Will Have Vastly Improved Safety Features

By JOHN P. LEE

TEW safety features being incorporated in the S.S. Ancon, recently launched, will make her and her sister ships the Panama and Cristobal the safest ships in the world. These new vessels will be operated this year under the American flag by the Panama Railroad Steamship Line in service between New York and the Panama Canal, via Haiti.

The trio of ships are the first American-built vessels to comply with the safety requirements drawn up several years ago by the Senate Technical Committee on Safety at Sea, headed by Admiral George H. Rock, and the sub-committee on Fire Control, headed by George Sharp, noted naval architect, to assist in the formulation of legislation for use by the Bureau of Marine Inspection and Navigation.

In order to create the circumstances of an actual fire at sca, the expeits conducted a long series of tests on an obsolete vessel, the S.S. Nantasket Single staterooms, as well as a group of adjoining staterooms, were built into the old ship. Various materials, including impregnated and untreated wood, asbestos compositions, aluminum, and steel, were used in the construction of the rooms. A space of three feet was allowed between the walls of the rooms and the shell of the ship in order to permit observation from the side.

Portholes were simulated by running vents from the stateroom walls through holes opened in the ship's side. An artificial non-recirculating ventilation system was also provided.

The tests involved three types of stateroom construction: 100ms built of steelfaced panels, with various type cores, of wood impregnated against fire, and of asbestos composition with special steel construction members or by orthodox joiner work methods using impregnated wood or asbestos composition. Some of the rooms were fitted with deck coverings, of various types, both within the test enclosure and on the deck above it.

To create a severe fire, cordwood and kindling, to the amount of five pounds per square foot of floor area, were stacked inside the room and, at a given signal, ignited at several points to produce a uniform spread of flame

Each fire was carefully timed by observers. Temperature readings within test enclosures were made from thermocouples variously located, one near each corner of the room and one in the center

TESTS showed conclusively that walls of substantial construction having panels of incombustible materials stood up without harmful bending or buckling, effectively confining the fire to the compartment they enclosed. Substances such as asbestos compositions, and corrugated and treated asbestos papers, were found suitable for such inner cores, faces of panels being steel, aluminum, or asbestos composition and in some cases with added thin veneers.

Under some conditions it was possible to employ thin combustible panel face vencers, combustible furniture, and combustible decorative trim without impairing the toom's capacity for fire confinement. Fire zone bulkheads or main subdivisions equipped with easily closed fire doors were also developed for keeping flames originating in machinery, cargo, or public spaces from spreading throughout the ship. Further protection against fire, it was found, could be obtained by covering the floors and deck with various type deck compositions.

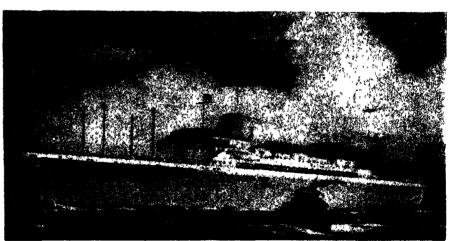

As a result of the fire test findings, all walls, ceilings, floors and other parts of the S.S. Ancon and her sister ships are being built of incombustible materials, so that any shipboard fire, no matter where its origin, can be confined within a limited are a.

Additional subdivision of structure safeguards the vessels against damages resulting from collisions or hidden reefs and will make the Ancon and her sister ships practically unsinkable. Each ship will be sub-divided into 12 separate compartments, any two of which may be pieceed simultaneously without affecting the ship's ability to stay affoat. Even if three of these compartments, under some conditions, are opened to the sea, the balance of the subdivisions will keep the ship affoat.

Never before used on any American ship, 'Schat skates' will be fitted to the lifeboats to insure their safe launching even if the vessel is leaning sharply to one side. Instead of being operated by oars, these lifeboats will be propelled by hand levers connected to the propellers, so that pasengers can operate them without difficulty.

The interior decoration of the Ancon is being done by Raymond Loewy, noted industrial designer who is making clever use of numerous fireproof materials, such as stainless steel, aluminum, glass, and plastics. Stainless steel, for example, is to be used on some of the furniture; aluminum is employed for chair frames and stair railings; plastics, compositions, or glass for table tops.

So complete is the attention of experts to safety aboard these ships that, in the words of the committee of experts, "the hazard of fire need no longer be a serious menace to the safety of life at sea."

Artist's drawing of the Ancon as she will appear when completed

THE STUBBORN ELEMENTS

THE story of element 87 presents a picture of the hard work, successes and failures, repeated promises and disappointments that have gone into the discovery of new elements. It also answers several possible questions that might be raised by the layman who seldom gets closer to such a discovery than reading about it in his newspaper

The first question such a reader may ask is; how does the searcher even know that such an element ought to exist? To answer this, reference must be made to that familiar old bugbear of students of elementary chemistry, the Periodic Table of the Elements, in which all fundamental relationships are revealed. In that table, the elements are numbered, starting with hydrogen as No. 1 and ending

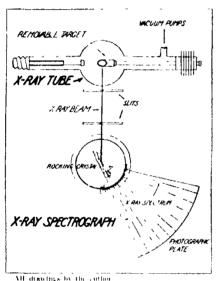

Figure l The old X ray spectrograph

with uranium, No 92 Now it turned out, many years after that remarkable classification was made, that the number of any element, that is, its so-called atomic number, also gives the number of outer elections in the atom of the particular element in question. When the table was first put together, many gaps were found, indicating unknown elements. Many of these were later filled in by various workers.

In the early days, it was easy enough to identify new elements by chemical means, but as each discovery was made, it left only the more stubborn cases for future workers, so that it became necessary to develop more powerful methods to detect new elements. Thus we arrive at the second question: how has the scientist known when he has a new element before him?

Some Chemical Elements Thrust Themselves Upon Us, Many were Found Chemically, but the Last Few Have Required Delicate Physical Methods of Search

By CHARLES W. SHEPPARD

The most commonly used instrument for making such identifications is the X ray spectrograph (Figure 1) This instrument makes use of the principle of X ray diffraction If a beam of X rays is projected through a crystal, such as calcite or rock-salt, a spectrum can be produced comparable with that formed when light goes through a prism or is reflected from a diffraction grating. This X ray spectrum is not visible to the naked eye. but if it is registered on a photographic plate, certain lines can be recognized Each line on the plate corresponds to a characteristic wavelength of X rays produced by the target of the X ray tube. If we use a special X-ray tube with a series of interchangeable targets, these lines are found to be distributed on the photographic plate just as are the lines in a spectrum-that is, in such a way that their wavelengths can be measured. Also, for each target used, the lines fall in different places on the plate, so that each target has its characteristic wavelengths

T was the clever young English physi-T was the ciever young Ling..... atomic number for each element was the number of external electrons in the atom With this discovery came a law concern ing the X ray lines of any element in an X-ray target Moseley's law states that the wavelength of these lines is inversely proportional to the square of the atomic number of the element. Therefore, if we know the atomic number of the element we are looking for, we can predict the wavelength of certain lines in its X-ray spectrum quite accurately (Figure 2). If we set up our X-ray spectrograph so as to catch these lines where we expect them to fall, then, if the element is present in the target which we have chosen to use in our X-ray tube, we should know it

This provides one good way to identify difficult elements, but it is well to have another to use as a check. One of the best of these, and one which is almost as sensitive as the X-ray method, is that of positive-ray analysis

Early in the present century, just about the time that satisfactory pumps were discovered for producing a high vacuum, positive rays, or 'canal' rays, were dis covered It was found that if an electri cal discharge was maintained in a low vacuum, a long, thin tube or "canal" could be led from the discharge to a high vacuum, and that, by sufficiently fast pumping, the high vacuum could be preserved (Figure 3). If this canal were then given a high negative charge, positive particles could be pulled from the arc with a high velocity and shot through the canal into the high vacuum. These par ticles were found to be atoms of the type present in the discharge but minus one or more outer electrons, which accounted for their positive charge. If we put any particular element into the discharge on the low vacuum side of the canal, we can produce positive rays of the element.

Now, a stream of charged particles acts like an electric current. So, if we put a magnetic field across the beam, the beam will be bent. However, the heavier particles are deflected less than the lighter, and if they then strike a fluorescent screen of a photographic plate, there will be a series of spots, one for each particular particle depending upon how heavy it is. This gives us a good way of finding just how much an atom weighs

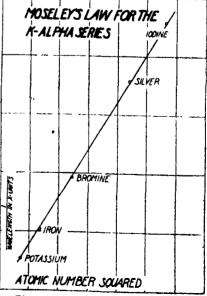

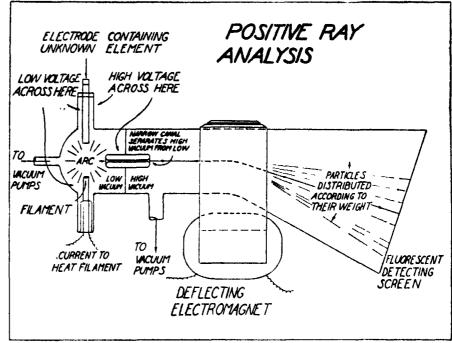

Figure 2: How Moseley's law works

and it has been a most useful device for this purpose. A conclusive way to identify a difficult element, therefore, would be to put it into such an apparatus to see whether we obtain a spot on our plate where we calculate that there ought to be one. Even better than this, if we do get such a spot, we can actually collect small quantities of the element in a pure state by putting some sort of collecting apparatus at this point. If we then examine these minute quantities with the X-ray spectrograph and get the proper Moselev lines, we are definitely sure that we have identified an element.

The next question one might ask is: where do we look for the element? To decide this matter, we obviously should determine its chemical properties. If we examine a Periodic Table, we find 87 in column I together with the alkalı metals, lithium, sodium, potassium, rubidium, and caesium. This would suggest to us that our element would behave like its fellows: it would react violently with water to make a caustic hydroxide. For similar reasons, it should have their strong affinity for chlorine, bromine, and iodine. It should be found in minerals rich in caesium. Since it is in the same row with elements like radium, uranium, and thorium, it should be radioactive Two minerals rich in alkali metals are lepidolite and pollucite. In 1929, at Princeton University, Dr. Bainbridge, using the method of positive-ray analysis, looked for the element in these two minrerals, but failed to detect it. It was felt that possibly he had not succeeded beforehand in concentrating the element sufficiently in the material to be examined. Prior to this, a number of persons had looked for it but without success

IN 1930, F Albson and E J Murphy, using a magneto-optic method, reported the presence of the element in the above minerals, but it was felt that their work was not sufficiently conclusive. In 1931, at Cornell University, J. Papish and E. Wainer reported finding X-ray lines of element. 87 in the mineral samarskite. These lines turned out to be false.

In 1936, H. Hulubei, in France, reported that he had found weak lines of 1032 and 1043 X-units (one X-unit is 0.0000000001 centimeters wavelength) on a large curved-crystal focusing spectrograph, an instrument very similar to the one described in Scientific American, May, 1932. These lines, he claimed, were the pair of element 87 called the L alpha doublet. However, a controversy arose, for in 1937, F. R. Hirsh, at Cornell University, reported that the lines were off by some six X-units, and it seemed much more likely that these lines were the L beta doublet of mercury which came at 1030 and 1037 X-units. Actually, mercury was known to be present, since it almost always is found in any X-ray tube which is connected to a vacuum pump of the

Liquie 3. Set-up of apparatus for positive ray analysis (see the text)

WHEN a man discovers a ton of gold or a stone in his shoe, he feels positively that he has made a discovery his senses tell him directly. And so it has been with most of the elements. Difficult elements, however, cannot be apprehended directly by our senses but require intermediaries: apparatus. And sometimes the evidence is so tenuous that science remains uncertain. Thus, after all, it is only relative-Iv possible to be sure of discov--as is true of all knowledge. —The Eduor.

mercury diffusion type. Hulubei had thought of this but based his claim on the fact that the lines persisted when he substituted oil diffusion vacuum pumps for his mercury ones. Nevertheless, it is felt among most X-ray spectroscopists that, once mercury gets in, it permanently contaminates the X-ray tube.

In this same report, Hirsh described an attempt to find the elusive lines in a concentrate obtained from California Using a target of this material, Hirsh took an eight-hour exposure on the same apparatus as that used by Papish and Wainer, mentioned above. This apparatus had a mechanism for rocking the crystal during the exposure which, besides producing the spectrum, prevents possible flaws in the crystal from producing false lines. This exposure produced a very good line at the center of the plate which had been placed where calculations showed the line would be expected. Hirsh then took a longer exposure, using a material estimated to be concentrated to about nine times the extent of that of the previous sample

The line showed up more strongly, However, although he seemed to be "getting hot," Hirsh felt that there was something peculiar about this line, so, in order to be sure that it was not spurious, he put a blank copper target in the X-ray tube and, to his dismay, found the same line on his plate as before. Undoubtedly it was due to a flaw in the crystal of his spectrograph. The crystal was then set to rock through a larger arc and the line vanished This line was the same one that Papish and Wainer had found on the same apparatus, so it seemed that the field was again open for the discovery of clement 87

It remained open until the fall of 1937, when Huluber reported that he had recorded several additional principal lines of 87. The instrument which he used is the equivalent in sensitivity of many single-crystal spectrographs in one, and if the discovery holds up, it would seem to indicate that previous failures by others were due to lack of sufficient sensitivity.

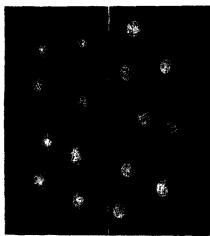

LET us draw some comparisons, Most of us have at some time or other seen a small mountain of scrap iron and known that there is much more than we as individuals could possibly use. Then, in considering rarer elements, we might think of iridium, minute quantities of which are used to tip better grades of fountain pens, and which costs about \$160 an ounce. In an even scarcer class are the elements of the rare earth group, most of which have never been isolated in the pure state. Finally, No. 87 is much scarcer, even, than these. Referring to pure caesium from pollucite, Bainbridge estimated element 87 to be present in amounts less than three parts in every 10,000,000 of this caesium and no doubt it is much scarcer, even, than that

Pearls Through Artifice

POR more than 4000 years, men and women have been fascinated by the beauty of the natural pearl. The possession of these jewels has brought to their owners that esthetic appreciation of elegance, rarity, and authenticity which is the basis of values in all gems and works of art.

It would be strange indeed if during all these centuries no imitations or simulations of this most warmly beautiful of all gems had been developed. The case of the pearl, in fact, has been that of nearly every other rare possession, in that many attempts have been made to reproduce in cheaper form an article resembling as closely as possible the natural jewel

But while imitation is said to be the sincerest form of flattery, the public is

Eight whole cultured pearls, left of line, compared with mother-of-pearl cores from eight cultured pearls of similar size. Cores not small grams

entitled to full knowledge regarding the differences between the authentic article and those made to simulate it. On this premise were developed the stamp of "sterling" on silver and of "24 carat" on gold, to distinguish them from the plated products, and to serve through law and custom as safeguards to the public and the ethical merchant.

It is felt that, up to the present time, the slow processes of law and public education have not yet brought about an adequate recognition of the differences between natural and simulated pearls. In fact, erroneous popular impressions have been reflected in published statements appearing in standard reference works.

In the case of the pearl, two lines of development have been followed in efforts to create through artifice products Man's Two Principal Methods of Simulating Nature's Gem . . . Misconceptions About Biologically Synthesized Pearl . . . New Research Uncovers Facts

By A. E. ALEXANDER, Ph.D. Pearl Fellowship, Mellon Institute, Pittsburgh, Pa

IN attempting to simulate the highly prized natural Oriental pearl, man has resorted to two methods-one entirely manual fabrication, the other a combination of manufacturing and biological processes. According to the findings of the writer, the Japanese cultured pearl is structurally different and physically less homogeneous than the natural pearl. Contrary to the widely accepted belief, all specimens examined contain a relatively large mother-of-pearl bead or nucleus and not a "tiny irritant"-in nearly all cases comprising 80 to 90 percent of the total diameter of the cultured pearl. The process of culturing pearls is, so to speak, the biological analogue of veneering wood or producing a plated metal.

that simulate the 11ch iridescence of the rare and costher natural gem. The first employs chemistry and ceramics to produce an imitation which is, of course, to be considered as a manufactured synthetic article.

The second line of development has involved a combination of a manufacturing operation and a biological phenomenon to produce the so-called "cultured" pearl In this procedure, an oyster is induced by irritation to enrobe a manually inserted mother-of-pearl bead-which in the present commercial article is relatively large in size--with concentric layers of nacreous material. This combination of operations and structures is unique as an industrial technic, an arnele so produced is in part manufactured, and the process is, so to speak, the biological analogue of veneering wood or producing a plated metal.

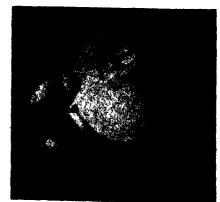

Methods for producing artificial pearls were recorded over 200 years ago, and doubtless many attempts go back still further Two general types of imitations are manufactured, one employing a solid glass bead and the other a hollow glass sphere. The former are prepared by coat-

ing the glass core with a wide variety of substances, usually a lacquer to which "pearl essence"—essentially guarine, obtained from various species of fish—may be added. The hollow glass spheres are coated internally with "pearl essence" and are weighted by loading with wax and barium sulfate.

In 1935, 15,615 hollow or filled nidescent imitation pearls were imported into the United States. In the same year 86, 375,289 inches—the unit in which importations are reported—of solid imitation beads of varying quality, with a total valuation of \$49,803, were brought into the country. Of this number 81,392,590 inches were made in Japan.

A subsequent article will be devoted entirely to natural pearls At this point it should be mentioned, however, that the formation of a pearl in a pearl-bearing oyster is a biological accident. Furthermore, it is interesting to note that by a curious paradox of nature this loveliest of gems is believed to be the result of a pathological condition.

The most ingenious development in pearl artifice has involved bending these natural processes to mass production methods. The original conception on which this industry is based is attributed to the Chinese. As early as the 13th Century, they discovered that, by placing an object—such as a small image of Buddha—in a living mussel and returning the

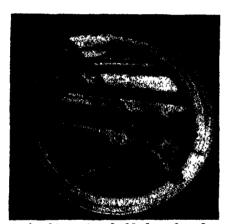

An imitation pearl—a glass bead, lacquered. Note thinness of coating which has been partially removed

mollusk to its natural environment, a deposit of nacre was slowly built up around this nucleus.

In 1890, in Japan, was begun the present-day commercialization of this Chinese discovery. It is indeed a feat of industrial biology, which may be compared in ingenuity with the accomplishments of the chemists in producing artificial rubies and sapphires. The founder of the industry, Kokichi Mikimoto, after many discouragements, succeeded in producing blister pearls about 1894. A decade or more clapsed before he was able to obtain a spherical form.

The following detailed description of the production of a cultured pearl is taken from Japanese sources:

"The process consists of removing from a living oyster the mantle parenchyma which is used as a bag to envelop the nucleus of the pearl. When this nucleus, which consists of a tiny fragment of fresh water mussel, has been inserted in the fleshy bag, its mouth is secured with a cord, and the whole is introduced into the subcutaneous tissue of the shell-secreting epidermis of another oyster through an opening surgically made for the purpose. In the same operation the cord is withdrawn, the wound made by the lancet is disinfected, and the oyster having been returned to the sea is left to cover the

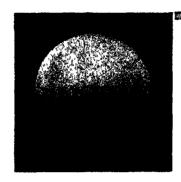

A thin-sectioned black cultured pearl. Note fineness of laminae and "grain" of large core. This pearl was originally drilled off center

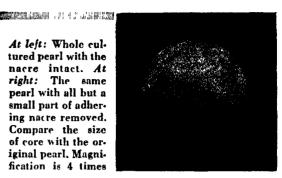

nucleus with the many layers of nacre necessary to produce perfectly spherical pearls.'

The concentric rings in the natural pearl and in the outer section of the cultured pearl doubtless are related to some periodicity in the life processes of the oyster. In analogy to annual rings in trees, they might permit an approximate estimate of the period of growth. This information may be known to the Japanese producers, but it has not been published so far as we are aware.

In a thorough examination of a representative collection of several hundred cultured pearls, it has been found that, contrary to the general impression, the cores represent the major part of the

At left: Whole cultured pearl with the nacre intact. At right: The same pearl with all but a small part of adhering nacre removed. Compare the size of core with the original pearl, Magnification is 4 times

article By means of a specially constructed micrometer gage used in conjunction with a binocular microscope, the writer has observed that, with few exceptions, the linear diameter of the core is 80 to 90 percent of the whole diameter. The outer shell of nacre is, therefore, comparatively thin. The widely accepted popular belief that the nucleus of the biologically synthesized pearl is a "tiny irritant," apparently rests on such statements as: "this nucleus, which consists of a tiny fragment of fresh water mussel. etc.

The nucleus consists of mother-ofpearl substance-ordinary calcium carbonate with an adhesive protein constituent-which has been manufactured from mollusk shells. This core or bead is shaped into a sphere by mechanical means and is then given a high polish

MONG procedures used in this inves-A tigation as well as by other scientific workers for the study of pearl material, are the usual chemical and physical tests and X-ray radiographic technic. The petrographic microscope has revealed particularly interesting information in the writer's research by permitting more searching examination of the structure of exceedingly thin sections. In the natural pearl the nacreous material has been deposited in very fine concentric layers throughout the jewel. In the cultured pearl the comparatively large core, as would be expected from its origin, is found to be built up in distinct parallel layers. The outer shell of nacreous ma terial is seen to consist of concentric lavers. The mineral matter is aragonite, the orthorhombic form of calcium carbonate. although in a few cases calcite has been encountered.

Because of the external characteristics of the shell of pearl matter, the layman may feel that the cultured pearl and the natural gem appear to be the same. By expert visual examination, however, and particularly by the use of special physical apparatus, the two can be differentiated. As in the case of other objects of esthetic value, it is necessary for the uninitiated to rely upon the knowledge of the expert, who by training and experience is qualified to reach authoritative conclusions on such matters.

The Japanese cultured pearl, with its margaritic substance around a motherof pearl bead, does not possess to a similar degree the mechanical homogeneity of the natural pearl. A knife edge applied to the surface, when struck with a light mallet, usually causes the outer shell to break off in whole or in part. Natural pearls show a different type of spalling, permitting the conclusion that the concentric structure does not have a zone of separation or weakness.

As an additional procedure for the examination of drilled cultured pearls, it was found that when a dye solution, such as methylene blue, is inserted into the bore by means of a fine needle, the color spreads at once throughout the zone of separation between the inner core and the outer nacre. The phenomenon is readily followed by the use of a microscope. When this test is applied to natural pearls, no penetration of dye takes place. It has been reported that this property of cultured pearls has been taken advantage of, to an extent that is not known, by dyeing them to improve color and appearance and to simulate the inherent characteristics of such special types of natural pearls as the black variety. We have observed specimens which give evidence of having been subjected to such treatment.

Accurate figures on the number of cultured pearls produced and marketed are not available. For several years prior to 1931 it is reported that an average of about 3,000,000 oysters were set annually, and in 1931 this number was increased to more than 6,000,000. Of the total number of oysters set, it is said that only 60 percent will produce cultured pearls of salable value.

The cultured pearl industry in Japan is "big business" and for that reason it is casy to believe that the number now being produced in Japanese waters exceeds by millions the quantity said to have been obtained in 1931. Labor in Japan has been both cheap and plentiful, especially so since women are well suited for this type of work.

The situation is further complicated by the fact that the business of reproducing cultured pearls is no longer confined to Japanese waters. Advertisements mention the South Sca Islands and an examination of some specimens reveals characteristics not found in Japanese cultured pearls. The extent of the industry outside of Japan is not known.

OTHER DAYS IN PHOTOGRAPHY

IN 1839, just a century ago, Daguerre announced his discovery that an image could be formed by light acting on an iodized silver plate. Then followed the tremendous popularity of the Daguerreotype, first successful forerunner of our present-day photographs. Through the Callotype and the wet-plate process, the collodion and the gelatin emulsions, progress was steady but slow Only with the advent of flexible film did photography receive the impetus that has made possible the highly efficient cameras, films, and printing papers which we have today. The accompanying illustrations show some of the difficulties under which photographers labored during the 19th Century

Right: A roof-top photographic studio of the 19th Century. Strong sunlight was necessary for picture taking, and the ex-

posures stretched to seeming eternity—for the subjects. To keep the sitter from moving during these long exposures, an "immobilizer" was used

Left In the days of the wetplate process, the photographer had to coat his own plates in the darkroom. First he cleaned the glass thoroughly, then coated it with collodion and sensitized the surface. Plates had to be exposed immediately, before the collodion had time to dry out

An amateur photographer of the 1860's starts out to take a few pictures. He had to carry, in addition to his camera, dark-room and wet-plate-making equipment!

"On location," the darkroom tent is set up, a plate is coated, and an exposure is made at once. The photographer's assistant is ready with a newly sensitized plate

THE HYSTEROID PERSONALITY

While the Paranoid Type Aggressively Hews to the Line and Faces Facts, the Hysteroid Personality Seeks to Evade Difficulties by Sidestepping Reality

By PAUL POPENOE, Sc.D.

Director, The Institute of Family Relations, Los Angeles, Lecturer in Biology, University of Southern California

HEN an animal faces danger, it may react typically in one or the other of two contrasted ways: it may advance and attack; or it may retreat, run away, and hide. These primitive biological reaction-types color human behavior just as they do that of a tiger, a shark, or a scorpion. Greatly extended and variegated, they result in two contrasting types of human personality.

The paranoid follows the attack-pattern. The man (or woman) with a typical paranoid personality is always on the aggressive. He is not merely ready to meet trouble when it comes: he is looking for it, and is prone to imagine it where it does not really exist. His whole life tends to become a fight.

The hysteroid follows the other pattern. The man (or woman) with a typical hysteroid personality is always on the defensive, always trying to escape, not merely from real but likewise from imaginary dangers. His whole life tends to become an evasion, a sham, a pose.

There is a difference in the complexity, in the diversification, of the two types of personality, which reflects the differences in nature.

In general, there is only one way to attack an enemy: you simply attack him You go after him tooth and nail Corresponding to this, the paranoid pattern sometimes seems therefore to be fairly simple. By contrast, there are a lot of ways of escaping from an enemy. The animal may simply flee, depending on speed, as does the antelope, or it may. instead, dig a hole in the ground and crawl into it, as does the badger. It may pretend to be injured, as does the quail suddenly startled from her nest. It may pretend to be wholly dead, as do many msects and other animals, proverbially the opossum. It may change its color to become inconspicuous, as does the chamelcon. It may throw out a cloud of ink to color the water and hide itself, as does the cuttle-fish. It may make itself offensive, as does the skunk. It may mimic an

'See "The Paranoid Personality," by the same author. Belefitific American, February, 1938, pages 74-77,--Ed.

offensive species, as some insects do, so that enemies, confused, will avoid them It may, though harmless, look so hideous and formidable as to scare away marauders.

One could find types of human behavior corresponding, figuratively, to all these and many other animal patterns As methods of escaping trouble, they may properly be brought into the general picture of the hysteroid personality

Historically, the term hysteria has a

Among famous persons, Tolstoy has been mentioned as a hysteroid type

more limited use, applied particularly to physical conditions. Hippocrates, the Greek "Father of Medicine," described various vague and fluctuating symptoms in women, which he explained by supposing that the womb (hystera) wandered around in the body seeking humidity and, by transient pressure on various structures, caused transient symptoms of discase.

Modern biologists naturally take a less naive view of the physical basis of hysteria. They would relate it to two of the most primitive and deep-seated nervous mechanisms of the individual.

One of these is the tendency of an animal to make violent and spasmodic move-

ments when trapped or frightened. Thus a bird, flying steadily enough, finds itself suddenly inside a porch. It beats violently against the windows and walls until it accidentally finds a way of escape, whereupon it once again begins to fly as evenly as before. The other mechanism is the sham-death-reflex as seen in the opossum.

In the case of a great shock or panic, such as might accompany an earthquake or holocaust, many persons are said to become "hysterical." They rush around wildly and apparently without reason, as does the bird trapped in a room. On the other hand, many fall into a sort of stuporous state (like the opossum) in which their behavior is irrational but actually, no doubt, serves the purpose of protecting the nervous system from further shocks that it could not withstand. Plenty of illustrations of both types of behavior were seen in soldiers during the World War.

ACTING through such fundamental mechanisms in the organism, the strong primal urges of self-preservation (fear, as in wai) and species-preservation (sex) produce "hysteria." The process is, diagrammatically, something like this: (1) desire to escape from danger. (2) suggestion of a way of escape, (3) accidental escape through the way suggested (that is, some "symptom"), (4) fear of return to danger with recovery from symptom, (5) exaggeration of symptom, (6) fixation of symptom through the usual methods of habit-formation, (7) final existence of the symptom without any cause.

To make the picture more concrete, take such a case as occurred over and over again during the war. N. was knocked down by the concussion of an exploding shell. Of course he was bound to be somewhat injured. His aim was bruised. He was taken to the hospital and bandaged.

His whole being revolted against going back into danger. It was easy for him to "discover" that the arm was more seriously injured than the doctors thought. It did not get well—it became paralyzed. He had to be sent away from the combatant sector because his arm, now paralyzed, made him useless there.

His arm really is paralyzed now: but it a functional paralysis, a hysterical paralysis. He is not malingering—that is, not consciously pretending. The whole process is unconscious but none the less real. He is sent to a convalescent camp His arm shows no improvement: the war

is still on. Then the announcement of the armistice is broadcast. He no longer need fear going back to the trenches. He no longer needs a paralyzed arm. Hence his arm begins to get well. The mere announcement that there would be no more fighting cured, sometimes almost miraculously, hundreds of soldiers with these hysterical disabilities ("shell-shock").

Such a case represents, in simplified diagram, the "classical" form of hysteria—the simulation of a disease as a protection against danger.

Anyone is theoretically capable of hysteria, because all have these fundamental biological mechanisms; but some are much more easily affected than others Women are more susceptible than men, as Hippocrates recognized when he ignorantly picked out the womb as the source of trouble The main psychological difference between the sexes, as reported by Terman and Miles in the most comprehensive study yet made ("Sex and Personality," 1937) is the greater aggressiveness of the male. Hence the paranoid personality is more likely to be found in men. Women will be more ready to escape than to advance and attack, hence the hysteroid tendency is more often distinguished in them. But since any woman can fight and under certain circumstances will do so; and since any man can and may run away, the possibilities of both types of behavior are present in both sexes.

Though contrasted, the two types are not mutually exclusive: all of us have some tendencies in each direction. It is only in pronounced cases, where the balance is greatly on one side, that we speak of the paranoid personality or the hysteroid personality. Most of us are betwixt and between

THE pronounced hysteroid personality represents a special make up that apparently depends to a considerable degree upon heredity. The following components tend to be present in varying amounts:

- 1) A tendency to easy dissociation of the nervous system. This is characteristic of the extravert, not the introvert, and pronounced hystericals are likely to be of the extravert type. One part of the consciousness can be "split off" from the rest, as when a person is hypnotized. This makes possible the striking physical manifestations such as the genuinely paralyzed arm of a soldier who is organically sound. Hysteria may simulate almost any disability in this way.
- 2) An imperfect development of the organism, a physical infantilism. This is often seen most clearly in the reproductive system, but presumably may characterize the whole organism.
- 3.) An emotional infantilism Though adult by the calendar, the individual has retained the infant's characteristic egocentricity, selfishness, suggestibility, lack

of self-control, vivid imagination, and immaturity of impulse. "Who, in the examination of a hysteric, has not hundreds of times cried out that he had a big child before him!" observed Pierre Janet, the French neurologist who gave the modern concept of hysteria much of its form. Really superior persons are rarely found to show symptoms of hysteria (a term now generally reserved for physical manifestations such as the paralyzed arm). They may have the hysteroid personality in some degree; but those who have it so markedly as to show striking results of dissociation are likely to be personalities that are undeveloped and poorly put together anyway. The history of witchcraft and of miraculous "faith cures" will yield any number of illustrations.

While the biologically defective personality marked by the three traits I have just named is most likely to make conspicuous-indeed startling-use of the escape mechanisms underlying a hysterold personality, all of us have some tendency in that direction, as I have previously emphasized. The traditional "Sunday morning headache" which makes one feel that going to church would be harmful and that a game of golf or a trip to the beach would be more desirable-in fact necessary to well-being-- is merely one of the everyday forms of hysteroid mechanism. Who of us will declare that he has never taken refuge in such an evasion?

Remembering that the purpose of hysteroid behavior is to escape from unpleasant, unwished-for, or dangerous situations, one can see how simulated illness can be used in a variety of effective ways:

- 1) To escape from threat to one's life, as in the war-time hysterias of the "shell-shock" type.
- 2) To escape from some other situation that is feared as dangerous Miss Q is afraid of sex, fears marriage, and therefore becomes a chronic invalid as a means of self-protection. Her relatives won't insist on her marriage, in that case
- 3) To escape honorably from responsibility. An important function of the hysteroid mechanism is to enable one to keep his own self-esteem, to "save his face," to think well of himself, at the same time that he runs away. Many a woman, faced by an invitation which she wants to decline, finds herself too unwell to attend. As is often the case with the hysteroid personality, conscious and unconscious deception blend into each other so closely that no one can draw a line between them. One of the characteristics of the hysteroid personality is its great capacity for self deception The woman who does not want a visit from her mother in-law may take to her bed with a spell of indigestion just as real, in its way, as the soldier's visibly paralyzed arm.
- 4.) To escape from neglect, that is, to get attention A large part of the every-

day hysterical manifestations are of this type. The hysteroid, being essentially a spoiled child, with all the spoiled child's selfishness, conceit, desire to show off, and indifference to the interests of others, is continually getting attention by being unwell, being delicate, needing special care. Mrs. C., like ten thousand other dissatished wives, governs her husband and dominates the whole family in this way She must not be "crossed" because it will affect her so unpleasantly. She must always be humored, catered to, toadied to, because she deserves so much sympathy. Her life is such a burden to her that the least we can do for her is to try to give her a little pleasure. And how she does "enjoy ill health!"

5) To escape creditably from the consequences of some personal deficiency. Mr. L. 15 a tennis player-not a very good one but with enormous self-esteem Like typical hysteroids, he plays only to win. He is not too scrupulous in his code of sportsmanship. If he loses, there is always a good reason. "I knew I wouldn't win today I was miserably sick all night", or 'I didn't try this afternoon, my head was aching so badly that all I could do was wonder whether I could get through the last set without collapsing on the court." In such circumstances, you are supposed not to depreciate his ability but rather to admine his fortitude, to praise the plucky fight he put up against what he knew to be overwhelming odds! When he once reached the semi-finals and faced an opponent sure to defeat him, he "had to" default through illness, he went to the hospital with one of his spells and sent a pathetic telegram regretting the loss of the cup when he felt that it was right in his hands.

EAVING now the classical form of genuine hysteria, it is important to follow the hysteroid personality out into its borderlands where it is manifested by mental rather than by physical symptoms. One will encounter, in such an excursion, a wide range of escape mechanisms such as have already been described among the lower animals.

Thus a man may escape danger and save his face, not by "flight into illness" but by flight into obscurity. As the cuttle-fish conceals itself by a cloud of ink, so a man may conceal himself by a cloud of rhetoric and mysticism. Followers of various superstitions (astrology, spiritualism, some of the "New Thought" cults) surround themselves with a mumbo-jumbo of big words and meaningless ideas which make them feel very superior and protect them from having to compete in everyday life. This, like the form of escape preceding, shades off imperceptibly into an inferiority complex of the ordinary, uncomplicated type.

The underworld of the arts is inhabited largely by hysteroids. Faddist cults which

claim exemption from all the rules of physical and natural science form an excellent example of hysterical mimicry -the attempt to gain prestige by sham and wishful thinking. The hobohemians and Greenwich Villagers (using that term in a spiritual rather than a geographical sense) who take up post-ultrasuper-modernism in art have in many instances found an exceedingly effective way of escaping from the danger of having to earn a living, of having to succeed by open competition in the world. Would-be actors and actresses likewise live on pose rather than on performance, in many instances. Anyone acquainted with this lunatic fringe of fakers and posers around the world of art cannot help being impressed by the infantile and disorganized personalities that comprise it.

The French novelist Stendahl (Henri Beyle) is a good illustration at a somewhat higher level. He loved falsehood and dissimulation just as a matter of "art for ait's sake." He changed his name; he filled his books and letters with deliberate and useless falsifications of dates and places, he could not even R.I.P. under the truth but had a false hood engraved on his tombstone

If we emphasize the trait of abnormal susceptibility to the determination of one's ideas by one's own wishes, we can follow the hysteroid personality into another wide field of human activity where Don Quixote has been named as the perfect literary illustration—always investing his surroundings with the forms that he wanted to see in them. It has been remarked that most of Ibsen's heroes and heroines (notably Peer Gynt.) are typical hysteroids.

Turning from fiction to history, Napoleon I is worth noting as a typical paranoid who also had strong hysteroid tendencies that became more pronounced in his later years. During the Russian campaign, he was continually making himself believe that his forces were much greater than they really were, that the enemy was weaker than it really was; and his staff were often at their wits' end to combat this infantile behavior and to make him face the facts. His callous egotism and ruthless dishonesty are also typically hysteroid. When a man of first-class ability has pronounced paranoid and hysteroid tendencies at the same time, he is likely to be a first-class menace to his fellow men!

Politicians tend to fall into two separable groups. One is made up of the paranoids—aggressive, domineering, driving ahead ruthlessly, crushing opposition relentlessly; stubborn, suspicious, helligerent—a type illustrated by some political bosses in America and by such well-known figures as Georges Clemenceau and Thaddeus Stevens. The other is made up of the hysteroid type—posers, gifted

with imagination and continually dramatizing themselves before the public. "Their natural bearing is pose," says O. Bumke, the German psychiatrist, of hysteroids in general.

Not to name any living worthies, probably at least a touch of this hysteroid element could be seen in men eminent in such diverse ways as Disraeli and Talleyrand, Alcibiades, and Thomas Jefferson; much more than a touch of it in the late Huey P Long. When one passes to the small fry, the hysteroid tendencies are often paramount, and not always the

Wagner, the composer, is thought by some to have been a hysteroid type

pleasant hysteroid components, either—too often the unpleasant ones such as sham, dishonesty, double dealing, callous disregard for the rights of others, readiness to repudiate legitimate obligations—anything to get ahead

ALL this is just the opposite of the typical paranoid's behavior. Stubborn and persistent, he is the man to stand up for a principle, right or wrong; to die in the last ditch rather than abandon the "cause." The natural history of politicians deserves particular consideration because it furnishes excellent material to differentiate the behavior of paranoids on one side and hysteroids on the other

Needless to say, the hysteroid personality is a prolific breeding-ground for criminal behavior. It will be found more rarely among those convicted of crimes of passion. It is almost universal among those convicted for crimes of gain—the white-livered crook who is trying to "beat the game" and get something for nothing; the double-crossing racketeer who is convinced that "only saps work." Indeed, the best known scale for measuring the hysteroid component of the personality was standardized by being given to convicts in a state prison!

This type of hysteroid blossoms most exuberantly among the "big shot" frauds and swindlers, the bluffers and confidence men who get even more satis faction from strutting across the stage and "putting one over" on the public, than from their actual gains. Joseph Balsamo, who called himself Count Cagliostro, is one of the outstanding historical examples; John Law of the Mississippi Bubble another; Horatio Bottomley, once a member of the British Parliament, a third. For American examples, one has merely to look into the daily newspaper. The big business world contains too many; the business underworld is largely made up of them.

There is a hysteroid sort of "philan-thropist" who represents—whether male or female—the worst traits of the "Lady Bountiful" type, an ostentatious and hypocritical humbug, dishonest in private dealings but loud in his pious protestations on the public platform. There is at the other extreme a hysteroid type of pauper—the whining beggar, apt at evasion of all responsibility, preying on society, living by deceit and occasional crime, satisfied with himself and completely lacking in sympathy for others.

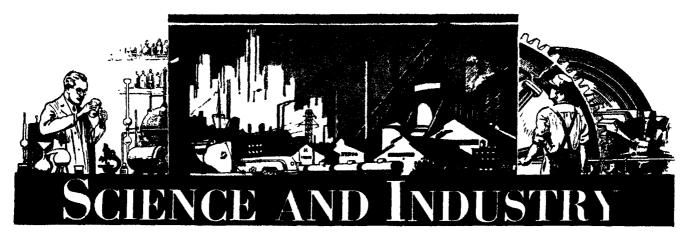

[N short, the hysteroid personality can In short, the hysterious production be found in every walk of life. When combined with strong impulses to selfassertion, and associated with inborn talent, the hysteroid's dramatic flair and his ability to make his wishes seem real to himself may lead to great achievement, most frequently in the field of art, religion, or politics. Among eminent men who have been named by one writer or another as hysteroids are Berlioz, Blucher, Flaubert, Frederick the Great, Goethe, Moliere, Muhammad, Nietzsche, Pascal, Rousseau, Schopenhauer, Strindberg, Tolstoy, and Wagner. The reader's own predilections will color his judgment but everyone will agree that at least some of those named belong among the hysteroids.

If the extreme hysteroid has a different type of constitution from the average person, it is evident that both prevention and cure will be difficult.

"Spoiled child" tendencies appear early and are largely fixed during adolescence. An education that prevents the development of a "spoiled child" will prevent the development of a hysteroid. Most is to be hoped, therefore, from a better technique of child guidance.

In dealing with an adult, one tries to make him see why he is sick, but also to give him a desire to be well. If the cause can be removed—if the patient can be made to face his situation honestly, and can be re-educated to make a superior sort of adjustment—his whole career will be changed.

But it would be optimistic to think that much can be done with an inferior, infantile, disintegrated adult who is making use, to his own great satisfaction, of such primitive biological mechanisms as are the basis of the hysteroid personality.

A MONTHLY DIGEST

PROSPECTORS NOW DIVE FOR GOLD

AN ingenious method of prospecting for gold and silver has recently come to light. Rather than drill into the ground by conventional methods, certain prospectors are now diving to the bottom of lakes in

Ready to dive-for gold!

Canada in their search for rich gold veins and silver ore deposits.

Largely responsible for making possible this under water prospecting, is a device known as the McCaa Two-Hour Oxygen-Breathing Apparatus, a product of the Mine Safety Appliances Company Strapped on the back like a pack and weighing approximately 30 pounds, the equipment consists of an oxygen container, a face mask, and tubes to convey the oxygen to the mouth of the diver It functions without a pump, the oxygen being fed to the diver's lungs by means of an automatic lung in the equipment. This equipment, good for a two-hour immersion in shallow water, may be used in 40 feet of water for periods of one hour

Accepted among geologists is the fact that

Conducted by F. D. McHUGH

most of the mines found to date are close to bodies of water, and that the best ore seems to occur under lakes. It is on this theory that the under-water prospector bases his efforts and hopes. The diving prospector, after donning the apparatus, takes with him a water-proof flashlight and a geologist's hammer. The practice followed is to have one man remain on shore, the diver carrying a line and making signals according to a prearranged code. The equipment carried is heavy enough to hold the diver down, yet not too heavy to permit him to move with case with a swimming motion.

MOST POWERFUL PERMANENT MAGNET

THE most powerful permanent magnet in the world—one that will lift nearly 1500 times its own weight—has been developed in the Research Laboratory of the General Electric Company by W. E. McKibben

The magnet weighs 1 85 grams, or 1/250th

The powerful magnet (between finger and thumb) and its steel casing

1500 times its own weight

of a pound, and has been made to lift 2750 grams in tests. About half the size of an craser on the end of a pencil, it will lift a five-pound flatiron with case. The new magnet is several times as strong as those previously made.

The magnet is made of a material known as Alnico, an alloy of aluminum, nickel, cobalt, and iron. This alloy was first developed as a heat-resisting alloy which resisted scaling and deterioration at high temperatures. Research on the magnetic properties of alloys of this type was later carried on by Professor T. Mishima of the Imperial University, Tokyo, and General Electric perfected a process of heat treating by which the magnetic properties were more fully developed.

The new magnet employs the same alloy as previously used, but utilizes a steel sheath around the Alnico pellet to direct the magnetic flux against the keeper or object being attracted. The steel jacket also protects the magnet against demagnetization when not in use.

EXPLODING WALNUTS

A NEW method of shelling walnuts, recently developed at the University of California, uses an explosion to burst the shells. The shelling operation, which is done

by machine, consists of passing the walnuts over a circular saw which cuts an opening through the shell; blowing explosive gasair mixture into the nut; and finally passing the nut through a flame which explodes its gaseous content. This method of breaking shells avoids fracturing the nut meats, which are not affected by the explosive. The machine in which this series of operations is accomplished opens about 900 pounds of walnuts per hour.—D. H. K.

ANTHRACITE

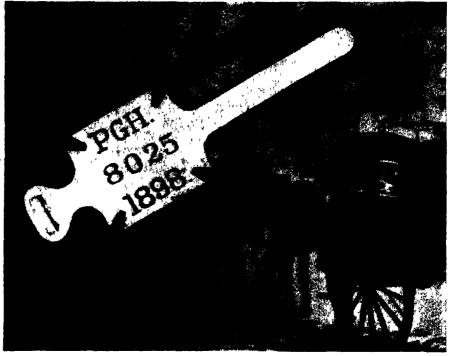

NEARLY 1,000,000 railway cars are required each year to transport anthracite coal, producing railway revenue of about \$100,000,000. All the railway cars required in a year would make a train more than 8000 miles long—more than enough to reach across the United States and back

Invention Helps Drainage Ditch Work

IMPROVED equipment for cleaning ditches is one of the by-products of large-scale work by CCC camps to put public drainage ditches in better condition. One new machine that promises good results was described by D. A. Isler of the U.S. Bureau of Agricultural Engineering before a meeting of the American Society of Agricultural Engineers. The machine consists of two winch drums on a truck chassis that has a light boom extending from one side for operating a scraper. It is used where dragline excavators cannot be used economically.

As Mr Isler described the use of the machine, dirt loosened in the ditch by plowing is removed with scrapers pulled by a cable from one of the winch drums. Another cable running over the boom from the other winch returns the scraper to the middle of the ditch for reloading. He said three such machines have been built by the bureau and are now in use at CCC drainage camps.

The machine can be easily mounted on and removed from practically any make of truck of 1½ tons or larger. The apparatus is mounted crosswise of the truck bed. Rigid blocking is provided between the rear axle

Grand-daddy of the aluminum license plates for automobiles, now being used in Connecticut and Arkansas, is this aluminum tag for horse-drawn hacks issued by Pittsburgh in 1898. It was of such shape as to be fastened around one of the shafts of the carriage, with the tongue of the plate through the slot on other end

and the truck frame to eliminate spring action and stabilize the truck while at work. The blocking can be removed for traveling on highways. The cost of the attachment, not including the truck, is estimated at \$1000. The outfit will handle 10 to 15 cubic yards an hour at a cost of 25 to 35 cents a yard lt is operated by a five-man crew.

Man WILL WIN WAR WITH INSECTS

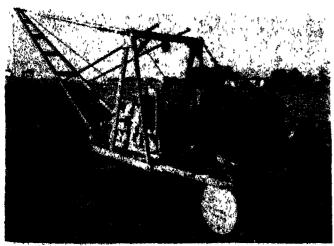

W AR between man and the insects, usually pictured as fraught with dire disaster to the human race, is going to end in victory for mankind, prophesied Professor J. J. Davis of Purdue University, in his address as president of the American Association of Economic Entomologists (See also "Insects Cannot Win" on page 222 of this issue.)

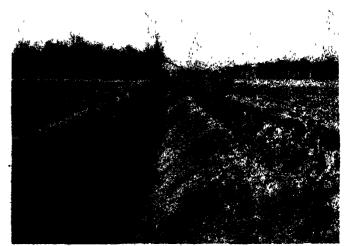

"When we realize that the science of applied entomology is scarcely more than 60 or 70 years old and note the progress in insect

control during that time," said Professor Davis, "we realize at once that man is gaining the upper hand. We may anticipate the time when our chemical, electrical, and mechanical warfare, insect-resistant varieties of plants and breeds of animals, and our farm and home practices, together with the aid of insect natural enemies, will reduce insect control to a routine, just as the medical profession has reduced or practically eliminated disease fatalities which were once responsible for the loss of thousands of human lives."

Victory will not come automatically, though, Professor Davis warned. Not merely eternal vigilance, but eternal research, is its price, for the front is always changing, as new crops are menaced by new pests, or as new business or social practices change people's relations to insects.

Professor Davis expressed the feeling that while it is now comparatively easy to get funds for insect control by known means, and to meet situations as they now exist, not nearly enough support is given to the research programs and the training of new

The new disch-cleaning equipment used by the CCC, left, and, at right, scraping a ditch

shaft. Meanwhile, the N.A.C.A. has been making tests in its full-scale wind tunnel, to determine the drag of a typical liquidcooled engine. These tests show that the engine nacelles of a four-engined model increase the drag of the whole airplane about 8 percent and the cooling (Prestone and oil radiators) system adds another 15 percent. As a result of these and other studies, it would appear that liquid-cooled engines should be placed within the wing; the ra diator should also be enclosed within the wing, with air led in through ducts from the outside. With the radiators placed at the largest cross-section of the duct, the drag increase is only 2 to 3 percent, as compared with the 15 percent of the conventional ar rangement mentioned above A. K

The control car of the K-2 is built into the hull. Note the airscoop in the slipstream of the propeller. Below. The K-2, largest non-rigid airship, landing

research workers, to meet new problems that will arise in the future. He pointed out, as an example of a problem of the rather immediate future, the necessity for knowing much more about insect infestations in stored grain, in connection with the evernormal granary project of the U.S. Department of Agriculture—Copyright by Science Service

HEAT VS. HUMIDITY

OMMON report has it that discomfort in the summer time is due not to heat but to humidity. However, in air conditioning for comfort, most systems so far in use are based on cooling rather than simple dehumidifying A new system, called "Caloride," actually does something about humidity and operates on the principle of reducing humidity to a comfort point without materially changing the temperature of the air. A special form of briquettes of calcium chloride are used to absorb moisture from air passed over them. The system uses ordinary city water as the only cooling medium and has no refrigerating machinery D. H. K.

LARGEST NON-RIGID AIRSHIP

WHILE the very large rigid airship is temporarily under a cloud, the much smaller non-rigids (commonly known as "blimps") are being built by Goodyear for both the Army and the Navy Such airships did perform many tasks during the World War which no other aircraft could undertake, particularly in locating submarines, in patrolling the North Sea, in destroying enemy mines, and so on.

There is every reason to believe that, no matter what advances may have been made in heavier-than-air machines, the blimps will still serve a useful purpose in what we must unfortunately call the next war. This is all the more likely as the blimps have themselves advanced considerably over the crude form which they exhibited during the World War. Thus with the use of helium, and with certain structural refinements, it is found possible to eliminate the cable sus-

AIR POWER IN
NATIONAL DEFENSE
SPEAKING of "Modern Air Power" at the annual meeting of the National Acronautic Association, Major-General Frank

pension of early days and the modern control cabin is built into the lower part of the hull. It provides comfortable quarters for a crew of seven—pilot. radio operator, navigator, mechanics. The old stove-pipe blowers have been replaced by neat airscoops placed in the slipstream of the propellers. The landing gear has become retractable.

With these various refinements the U. S. Navy K-2, largest non-rigid airship ever built (with 404,000 cubic feet of gas volume), has a speed of close to 80 miles per hour, a gross lift of 25,000 pounds, and a ratio of useful lift to gross lift which is so high that the new airship can cruise non-stop for several days. The two 550-horsepower Pratt & Whitney engines mounted in the outboard nacelles each turn three-bladed propellers 10 feet 6 inches in diameter.—A K.

ENCLOSING THE AIRCRAFT • ENGINE

NE of the most obvious possibilities for improvement in aerodynamic efficiency lies in the reduction of the drag of the engine and cooling system. Licutenant McCoy, reading a paper before the Institute of Aeronautical Sciences, strongly recommends that liquid-cooled engines should be enclosed within the wing, and that propellers should be driven through an extension of the motor

M. Andrews, Commanding General, CHQ Air Force, made it perfectly clear that the airplane has changed all conditions of warfare.

"Modern air power in future wars makes the picture different," said General Andrews "The ability of air forces to operate in three dimensions enables them to move over land and water without regard to obstacles on the earth's surface. Their freedom to select the time and place of attack, to operate during day or night and to use the clouds for concealment, makes adequate defense against air attack on a grand scale a serious problem Air forces, unlike ground forces, are not forced to wage an exhausting war at a nation's frontiers. The speed at which airplanes travel enables them to cover long distances in a short time. It is these characteristics of air forces that increase the power of the offense in war and make the airplane such a terrible instrument in the hands of un scrupulous governments.'

Discussing the range of the bomber in the same address, General Andrews points out that our ocean bulwarks are shrinking and that only a short time ago two British bombers flew non-stop from Egypt to Australia, a distance of 7160 miles. "I believe that any of our large airplane companies would be glad to contract to build a bomber capable of a tactical range of 10,000 miles, If American airplane manufacturers can build such

a bomber, it can be done in other countries."

The well-informed views of General Andrews, news from Spain, news from China, the Münich accord, all make it perfectly clear that we must put forth a real effort to retain air power. In the production and number of service airplanes we lag behind seriously, and the Administration program of building planes in large numbers comes none too soon.

But while acknowledging our lag in the production of airplanes, we have been accustomed to comfort ourselves with the reflection that if we do not lead in numbers we lead in aeronautical research and in the performance and fighting qualities of such air craft as we do have. Now the situation is changed regarding research. Thus, T. P. Wright, making his address as retiring president of the Institute of Acronautical Sciences, gives a pessimistic view of our position in aircraft experimentation and development. "A few years ago the United States was well in the lead in research, development, and production of aircraft, a fact attested by all who had the opportunity of visiting European countries at that time and of witnessing the scope of developments there I title could be learned from abroad at that time by Americans, Recently, how ever, visitors abroad have witnessed a great change. Many huge aeronautical laboratories have been established and are occupied in intensive research investigations. It is definitely established that the relative position of this country is reversed from 1931.

Brigadier-General W. G. Kilner, Assistant Chief of An Corps, also speaking before the National Aeronautic Association, took a similar point of view. Our supremacy in prototypes has disappeared, and we are falling behind in research and fundamental developments. Last year Great Britain spent fifteen million dollars on research in military aeronautics, France more than ten milion. No one knows what Germany and Italy spent for the same purpose We spent only six million dollars.—4. K

INACCURATE AIRPLANE BOMBING

IN our October 1938 issue Major Arthur E Oxley discussed at length the question of the military value of airplane bombing, and pointed out that airplanes nowadays are forced to fly at such high altitudes

that it is very difficult for them to hit important targets of military value.

Recent summarizing of the effects of the bombing of Barcelona in the Spanish Civil War bears out this conclusion. The records show that during the six days from December 5 to December 10, 1938, a total of 455 bombs were dropped by insurgent airplanes on Barcelona with the result that two people were killed and ten injured, while two horses were killed and one motor truck damaged. Obviously the only real effect must have been on property, for the residents of Barcelona had long since passed the point where air bombing did anything in particular to their morale.

The record further shows that during the course of the War this city was subjected to a total of 2000 air raids. Despite this extremely large number of raids, in which many thousands of bombs poured from the skies, no military objective was damaged greatly. The principal targets—the gas works and the central electric station—suffered only minor damages.

In view of these facts civilian populations everywhere will be reassured, though there is no question that much work has yet to be done in the matter of providing underground shelters such as were built in Barcelona.

Airplanes to Fight Forest Fires

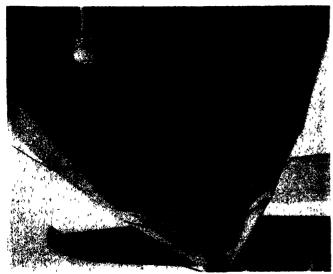

THE U. S. Forest Service has recently purchased a Stinson Reliant freighter model airplane, equipped with a 450 horse-power Wasp engine, for interesting experiments in fighting forest fires from the air.

Instrumentation on the ship is exceptionally complete to permit precision flying. In the bottom of the fuselage a special floor is incorporated (as shown in our photographs) with trap doors and a hatch opening 22 inches by 40 inches. Through this opening containers of water or fire-fighting chemicals can be released as desired. For cargo dropping work, guide boards are placed above the hatch opening. In addition to the hatch assembly and release gear, the ship is equipped with a new bomb-sight which gives a high degree of accuracy at low elevation. Military bomb-sights are in-tended primarily for high-altitude work and, aside from the factor of cost, are somewhat too complex for use in civil aircraft.

Before this new equipment can be put into practical service, a great deal of research will be necessary. The trajectory in space of mexpensive commercial containers must be studied. The bomb sight and release

Specially designed plane built for the U. S. Forest Service for fighting forest fires. Below: Views of the trap in the fuselage, shown open and closed

How the engine cowl of the interceptor fighter described below may be opened for convenient servicing of engine. Right. CH 21 in flight

equipment must be perfected. Then a new technique must be developed by which pilots and "fire bombers" will be able to protect our forests. Another medental study is that of dropping supplies, with the aid of simple parachutes, to fire crews or others cut off from usual methods of transportation.

This basic research is of great importance and value, and we wish the Service every success in its efforts—4. K

A GREAT INTERCEPTOR FIGHTER

THE Currow-Wright (# 2) Intercepting and Uniform the American State of the State of

It is cuitints to see what a midrary are plane of this type has to carry the weight empty is 3050 pounds, and the useful load of 1200 pounds; se divided up as follows fuel, 576 pounds, oil, 61 pounds, ordinates, 100 pounds, plut and paradium. 100 pounds, plut and paradium. 100 miss thaneous, 1/3 pounds. The gross weight fully loaded is thus seen to be 420 pounds, which is crowded into a relatively small machine with a span of only 35 feet.

One of our photographs shows the generally clean appearance of the CF/21 Another gives us an idea of the retractable landing goar and of the ready manner in which the engine cowl can be opened up for maintenance purposes. There are many other features in the design which desirve mention

Everyholy know that the palo's task in the modern plane is a heavy one, particularly because of the great number of matruments which he has to watch To reduce the difficulty of watching many instruments, as "cilcitat" were in suchded and the indicator gained contains eight sets of lights proper operating conditions. These lights signal immediately "Ford Press Low," "Off, "Mixture Lean," "Low Prop RPM," "High Blower," "Plaps Down," "Landing Gene Up." These titles of the signals speak for themselves.

creates wealth and opportunity where they did not exist before. Whereas the old order was based on competition, the new order of science makes possible, for the first time, a co-operative creative effort in which everyone is the gainer, and no one the loser."

STATIC SUPPRESSOR

UNITED Air Lines, co-operating with Bendix Radio Corporation, have produced a static suppressor for aircraft use which seems to have high promise. When the

chute and seat below, protect the pilot from

The detailed specifications of the CF 21 confirm the impression that a modern fight-ing striplane is an executingly complex affair, in which strength and aerodynamics are important part but are far from constituting all the elements of the design —A. K.

pilot presses a button, an electrical device and a steel spring installed at the extreme rear tip of the fuelsage release a wire into the slipstream which trails far behind the airplane. The wire is of very small diame ter—smaller than the size of the sharpert point on the airplane. Previous experiments have indicated that static interference of

Science and "The More Abundant Life"

GCH-NCE. has made provide a "new Jung under the son"—the more above that life generally distributed, without one man having to make his gains off another man's losses. Revarth in pure scence mids receive public support if this happy state of things is to be stabilized and extended. These were the man theses of Dr. Karl. Tompton, president of Massachments the opening session of the Turb Derdorn Conference of Agriculture, Industry, and Science, reported by Stence Service.

In pre-eximatic ages, Dr. Compton pount of out, advanced cultures arose, but their brillant accomplishments were always based on the exploitation of others. The Israelites gained their Promised Land only exterminating the Cananine nations already in possesson there. The Creeks and and learning, addisorship and have, only because they had alwest in the back of the house to do the hard and drivy work,

"But there is something new under the sun," Dr. Comption continued, "in that modern science has given mankind, for the first time in the history of the human race, a way of securing a more abundant life which does not simply consist in taking it away from someone clae. Science really

The static suppressor for airplanes is installed at rear of fuselage

ferst result from the uncontrolled ducharge of state electricity accumulating on the wangs and body of the arplane. With the trailing wire thanner than any possible discharge point on the rest of the plane, and a resistor to isolate the duckarge of the electricity from the vicinity of the airplane itself, aircraft static has been eliminated to all intents and purposes by its use. Of course, the anti-static loop antenna which we have had occasion to discuss before in these columns is still restained in the system. The jim-

portance of eliminating static when a pilot is listening for instructions or finding his bearings in bad weather cannot be over-emphasized.—A. K.

NITROGEN

FARM soils in the United States each year lose nearly 23 million tons of nitrogen through harvested crops, grazing, erosion, and learning, Only a little more than 16 million tons are given back to the soil in the form of fertilizers, manures, rainfall, irrigation waters, and learnee crops.

ELECTRIC EYE TRAINS FOR

A "PHANTOCYCLE" went into training recently for the world's first hundred thousand-mile inderless breyele race, scheduled to start next May at the 1939 New York World's Fair.

In the test run in the Westinghouse Research Laboratories at East Pit-hungh, this riderless bicycle, steered and halanced by a photo electric cell, chipped off 28 miles an hour, and the research engineers said it was ready to maintain this pace in a 365 day sprint, pacing off nearly 400 miles a day.

Unsupported by wires or braces of any kind, the beyele coasted along on three metal rollers, depending on the bettire cyc and a team-mate called Silverstat to keep the wheel upright. Two corrective weights fastened respectively to the handle bars and front mudgard and the groceopic effect of the becyele's front wheel added stability to the rdd rless wheel.

The electric eye is such a good inter that the beycle can bear a three-pound sidewise push against its saddle before losing its balance and falling into its safety catch. In fact, the electric eye is so good that it can steer the beycle without a quiver down the narrow groove formed by the three propulsion

The "beam" ride starts when a light beam strikes, under the pedals of the bicycle, a mirror which reflects varying amounts of light on the electric eye as the bicycle tilts from its upright position.

Sensing the tilting, the electric eye transforms the light energy into an electric current which is amplified and eletivered to the Silverstat which, in turn, controls a regulating motor. This motor, actuated by the electric eye, steers the front wheel of the bicycle and moves the two attached weights to balance the machine.

In this appearatis, the engineers explained of the bayely becomes a record of the bayely becomes a record of the bayely becomes a record of the bayely and corrects the tilting even before the balancing weight has time to shift its position. The corrols anticipator, foundable as its name counds, is only pair, foundable as its name counds, is only pair, foundable, as its name counds, is only a protection to grow, or twist, in proportion to angular velocity of precession. In this case, the angular velocity of precession is the velocity with which the front wheel of the haveles is secreted to left on rather.

SELF-DIFFUSING INCANDESCENT LAMP

LIGHTING cugineers recently welcomed a new type of glare-free electric light bulb, called the most practical improvement in incandescent lamps since the appearance

Old and new: Self-diffusing incandescent lamp contrasted to old type

in 1925 of the common inside frosted bulb. The new bulb, known as the Wabash Superlite, was developed by the Wabash Appliance Corporation.

According to Wabash, the new Superlite introduces light-conditioning in the bulb itself, producing soft, restful, surprisingly white illumination without the need for extra diffusing equipment or extra current. A new treatment on the inside of the glass breaks up the harsh raw light rays of the filam into soft, "counter-diffusing" light rays which are perfectly diffused over the entire bulb surface, and transmitted through the glass without loss of any light. Thus the "filamentfire" spot is eliminated, glare is stopped inside the bulb, and the light comes through perfectly conditioned for reading and working. All sizes of the Wabash Superlite, from 15 watts to 300 watts, are now in commercial production

RUBBER MOUNTINGS KEEP BELL IN BELFRY

I T looked for a while as though the new Bapust Church at Fries, Virginia, would have to break with tradition and install its hell in the yaid But thanks to rubber, tra-

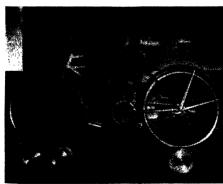

Bell mounting (in circle) to reduce vibration transmitted to belfry

dition won out. The bell now reposes in the tower of the church and everyone is happy about the whole thing.

The difficulty first arose at the time when plans for the new clurch were made. The church already owned a fine 1900-pound held which they warned to use. The plans called for a tower of ample size to house the held but to build it heavy enough to withstand both the weight and the vibration would increase the construction cost considerably above the amount appropriated for the structure. In view of this, it was agreed that the bell would have to be installed in the church yard.

However, after the church was completed, the architect was again approached by the congregation regarding the possibility of installing the bell in the tower. He again refused on the bases that, while the supporting timbers of the tower were strong enough to held the bell, the vibration created in ringing the bell would in time weaken the structure and night lead to an accodent.

Then one of the officials of the Washington Mills (large textile manufacturers located in

Ready to ride for a year, controlled by a photo cell

the same town) suggested that they try in stalling the bell on rubber mointings. As a result, it was mointed on four Vibro-Insulators supplied by The B. F. Goodrich Company. These rubber-to-metal, shear type-mointings are designed to carry a maximum load of 500 pounds, so one was attached to each of the four legs of the bell frame.

Tests were then made and showed that all damaging vibration had been climinated Thus, rubber permitted a tradition to be upheld at small cost and with complete safety

CHLORINATED RUBBER ON ROADS

ADDITION of small percentages of chlorinated rubber to the tar used on roadas a binder for their surface has been found to reduce the tendency of the tar to run in the summer and to become brittle in winter Tests of this idea are being made on British roads—D. H. K.

WIRE ROPE FIGHTS GAS WELL FIRE

WHEN a gas-producing well "goes wild" the proceedings are not simple Experienced fire fighters are not to be found in every community and, before they can be brought to the scen, the dangers and difficulties of fire fighting may have increased many fold.

minimum, after the valuable Rankmode Dr. Velopment Company's No 2 well bases into flame in Rankin County, Mississippi, it defe all efforts until the famous Pation Oil Well FireFighters, of Houston, Texas, came to the rescue. The well, which had been yielding approximately 30,000,000 cube feet of gas daily, was by this time a blairing informon The casing had split below the assembly of avokus familiarly known as the "Christianitee." Gas, at high pressure, was burning croom, "flames not only making the fire externelly difficult to fight, but also endangering the extra field to the cetter field.

Mr. H. L. Patton, president of the fire-fighting concern, who personally superintended the job, was confronted with quite a problem. If the fire was to be "snuffed out" by the usual method, it would first be netewary to control the flow of gas so that it

Mushroom-like flames, bursting from a split casing of a gas well, above, were snuffed out, below. after casing was cut with wire rope

would rise in a straight column, or shaft of flame. This meant that the Christmas tree would first have to be cut off and the split casing cemented, and allowed to "set,"

The heat was so intense that nobody could approach within 200 feet of the blazing well. Then President Patton had an a spiration. He bought 600 feet of %-inch 6 by 19 Yellow Strand Rope, together with large quantities of valve-grinding compound About 150 feet of the middle section of the rope was heavily loaded with the abrasive compound.

O. L. Patton, veteran fire-fighter, clad in

an asbestos suit, and with streams of water playing upon him, then approached closely enough to try to "lasso" the Christmas tree with the cable. After two vain attempts, the rope was finally thrown around the pipe below the tree. One end of the cable was held fast 300 feet away. The abrasive-loaded section was pulled tight against the casing Then after a complete circuit was made, each end of the rope was made fast to a tractor The tractors see-sawed the cable back and forth until the pipe of the assem bly was cut off cleanly and the flame roared skyward like a great plume. With the split casing cemented and set, the plume nar rowed to a towering pillar. Mr. Patton had more than his share of grief on this contract One of the tractors used in the "see-saw" process broke down the only bridge approach for the fire quenching apparatus, and a road had to be built over a water-sogged

The "sunfing" apparatus consisted of a derrick mounted on a trained by hoom car ried a manifold, which was lowered and fast nod over the pipe, the finance shooting out of its top. By shutting off a valve, the flow of gas was momentarly diverted, the oxygen supply was cut off—and the fine was out. Water was then injected into the well to counteract the gas pressure and the well was recapped.

NOVACHORD—NEW MUSICAL INSTRUMENT

A New muscal instrument, the Nonchord, based upon the principles of vibration, has just been produced by Lanrens Hammond, inventor of the Hammond organ. The new instrument holds a certain similarity to the piano and has been called an "electric orchestra," which is something of a mismomer. While the Novachord can produce tones resembling those of the mod augment the resonance of the contemporary piano, it is in no sense an imitation of any thing

In form, the Novachord resembles the old-fashioned spiner, having a single manual explorate of the played excepts as is a puno. It also has the regulation size of the puno. It also has the regulation trailed by a swell pedal similar to that of an organ. But here the similarity ends The thousand the punos of the Novachord are produced electrically by means of circuits of ordinary was unit tubes. A bank of 12 standard was-

These two groups of controls are used by the operator of the Novachord

num-tube oscillators, tuned to the 12 halftones in the highest octave of the instrument, supplies the original impulses from which all other notes are derived. Each octave, except the highest, uses "divider" tubes, the functions of which are to divide by two, exactly, the frequency received from the octavdove. In this way, the frequency of all the A's, for example, is controlled by the "A" oscillator in the top octave.

The tones of the Novachord can be varied over wide ranges by means of simple controls mounted on the front panel above the keyboard. These, broadly speaking, are divided into two groups:

The group on the left controls the actual tone color by varying the harmonics. The group on the right varies the so-called "en velope" of the tone, a term used to describthe speed of attack and decay.

The system works out in this way. If the controls at the left are set to produce the same harmonics which piano strings produce and those at the right are arranged to give he same percusive "envelope," the instrinent will produce tones similar to those of the ordinary piano.

If the left-hand controls are set to produce the harmonies of the violin and the right hand controls to produce a sustained tone, an effect of strings is produced with no change in the playing technique.

Hence, the bitter-sweet voice of the obor, the soft nasal tones of the hirrs ichord and

The Novachord

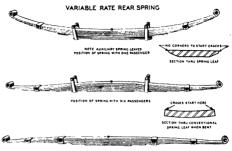

clavichord, the blare of the trumpets or the mellow ruminations of the French horn come forth accurately and without effort.

The music from the tone generator is amplified by conventional means and is heard through loud-speakers. The amplifying and speaking units are contained within the instrument, but for large installations where an unusual volume of sound is required, additional speaking equipment to any desired extent can be connected to the Novach-tad

VARIABLE-RATE SPRING FOR CARS

EVEN as modern a mechanical 1 arvel as the automobile had its beginnings 17 centures ago. The search for better spring ing methods kept even the earhest vehicle-engineers occupied. The history of springs, from their introduction in the third century to their climax in todays "Duflex" rear springs featured on the 1939 Pontiac, showlong and patient experiment.

The new spring is simplicity itself. To the conventional leaf spring, and directly below it, has been added a second but shorter leaf

1938 CONVENTIONAL REAR SPRING

spring. For light loads the car rides almost entirely on the main or upper unit which affords a slow, comfortable motion A; the passenger load increases, this upper unit comes progressively more and more in contact and the least respect to the contact and the least right and the least right would be sufficiently the least right and smoothly until full contact between the two units offers a maximum re-issance to diflection.

FEWER TERMITES GET More Attention

Is there more cancer, heart disease, and other disease today than there "used to be" or are modern faculties for reporting these diseases and gathering statistics simply superior to those that "used to be"? Many think the answer is the latter

Similarly, today one hears everywhere that there is now a new pest on earth, the termite, which is likely soon to reduce all our wooden buildings to shells which may eave in at any minute. We have always had termites, however, It is true, though, that we have become increasingly termite-concess, but this sonly in line with conscious ness about many another condition that was one neglected but today is noticed and one neglected but today is noticed and

fought against.

The United States Department of Agriculture has the following to say about ter-

"There are probably fewer termites in the country today than there were a generation or two ago, but these wood-destroying insects get much more public attention than they used to. Last year the Bureau of Entomology and Plant Quarantine answered more than 4000 requests for information about ter-

mites Inquiries came from every state in the Union.

"The number of termites has probably decreased somewhat, asys. R. A. St. Gorge of the United States Department of Agriculture. The decrease results, he says, from man's efforts to build homes in wooded areas, which necessitates the removal of trees logs, and stumps—the natural food of the insects— —and in some instances, the draming of most areas. Thus termites are deprived of their other man requirement, water,"

GAS-FILLED CABLE AN OUTSTANDING DEVELOPMENT

I OW. GAS PRESSURE, cable, most recent outstanding development in its field, is amounced by G B Shanklin, engineer of the cable section of the Gortrad Electric Company In the new cable, less insulation in required, los a given conductor size, than in the solid type of construction. As a result, not have been supported by the construction of the constitution of the solid types in existing duct systems without calargement of maniheax A present cost of the two types is comparable, and, particularly in the voltage range from 10 to 35 kg, it is believed that the smaller diameter and possible use in smaller standard diameters and possible use in smaller standard diameters and possible use in smaller standard diameters and possible uses in smaller standard through the same standard through thro

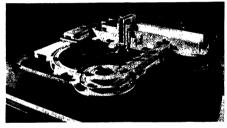

Gus channels in a new cable

The "roads of tomorrow" are being built today. Above; left: The Kew Gardens loop on Long Island and, right, the Pulaski Skyway in New Jersey. Below The Ford exhibit at the New York World's Fair, in which is half a mile of road

constructions. The new product is almost aseasy to handle in the field as is solid-type cable, and splices are simple. The adjustment of gas pre-sure can be handled economically by gas re-servoirs when conditions require them. An alarm system can be installed to detect gas leakage.

The general construction of the new calls a squite similar to that of the old-filled calles which are now widely used. The principal difference is that noted of being filled with gas-free oil, the channel spaces are drained called evident as filled with a neutral gas, introgen, under a moderate pressure (10 to 15 pounds per square inch). In his with his function of filling the gap between two earlier types of calle construction, its operating voltage stress, in volts per mil, is not a high as that of the old-filled type but is earlied with the control of the construction of the c

"THE ROAD OF TOMORROW"

ONE of the most significant steps in the development of modern highway construction is the consideration now being given by several state legislatures to the building of "freeways." Such routes were first proposed a few years ago but very little progress was made in having them generally adopted until New York and Rhode Island

passed the required legislation to enable their state highway departments to construct them. Among other states which are considering legalizing this type of road are California, Connecticut, Massachusetts, Maryland, and New Jersey.

The hasic essential of the freway is a right of way to which abutting property doenot have access. Because present traffic in hultup area is slowed down to an average of 15 miles an hour because of stephights necessary to control it while renoversaffic advances, it is estimated that the rate of travition of the stephing of the stephing of the car drivers can be multiplied many times if intersecting roads are eliminated.

Another major trend in safe express highway construction is loward elevated highways which separate local and express vehic ular traffic or all mostrored traffic from pedestrians. Such highways provide for a complete physical separation of upposing streams of traffic, chiminate direct access to abuting property, chiminate inter-extions and incidental cross-traffic, and separate pedestrian and vehicular traffic both laterally and crossand vehicular traffic both laterally and cross-

Taking a lesson from engineering experts who have definitely set the pace for elevated roads, the Ford Motor Company has constructed "The Road of Tomorrow" as an integral part of its Exposition building at the New York World's Fair. This road, which is more than half a mile long, rises by a spiral

ramp from the ground level to a maximum height of 33 feet, Over it visitors to the Fair will be driven in cars around and through the building at an elevation which prophetically demonstrates the treat toward the day when vehicular traffic will be separated from pedestrain traffic.

"The Road of Tomorrow" will be reached from the patio of the Ford Building by short stairs to a loading platform which will be provided with tables, chairs, and umbrellas. The ride istelf will be a delightful advinture, affording the passengers an unexcelled view of the enture Fair grounds and the surrounding countryside.

ALLOY HARDENED AFTER

FABRICATION

E ASILY fabricated in its soft state, a now mickel alloy takes on a high degree of strength and hardness following simple hardening treatment. Also, it possesses high corrosion restance. This "27" Nickel (98) percent nickel minimum) is now offered in various fabricated forms and different degrees of temper by the Driver-Harris Company.

In the unhardened or quench-annealed state, "Z" Nickel is as resdily worked as nickel, including bending, drawing, maching, and hot forging. When healt-ireated, however, at low temperatures of 890 to 930 degrees, Fahrenheit, it attains a hardness of Rockwell C 33-45, at which levels it is 2½ to 4 times as strong as structural carbon steel and possesses good toughness.

"Z" Nickel is being fabricated in colddrawn rods, wire, and cold-rolled strip, in a wide range of sizes. Such forms are avail-

pers to meet intended fabrication and anplication requirements. Since the extremes of initial softness and ultimate hardness determine the full value of this alloy to users, exceptional care is taken in rolling and drawing operations The new alloy finds many applications,

able in soft, half-hard, and full-hard tem-

already including coil springs, spring clips, wire brushes, hand tools, and other items. It lends itself particularly well to deep drawing of parts that must withstand exceptionally hard usage

HAND POWER-SANDER

RINGING new speed, efficiency and convenience to metal and wood workers, a nine pound, portable electric belt sander has just been announced by the Syracuse Guildtool Company, Featured by its handy compactness and moderate price, this new power tool was especially designed to make available to the average workman the advantages

of the belt-type sander, and to eliminate the costly drudgery of hand sanding, surfacing, and refinishing

Light in weight, the GuildSander is usable in any position. It has the power to do all types of sanding and the adaptability to sand all straight or slightly curved surfaces. The front pulley may even be used as a spindle sander.

In quality, the GuildSander conforms to the recognized standard of larger and much costlier portable sanders. It is built with a die-cast aluminum frame, finished in baked aluminum enamel. The abrasive belts are of the endless type, and travel 600 feet per minute. They are two inches wide by 21 inches in circumference, and are furnished in all usable grits They may be changed quickly

The GuildSander is equipped with 110-volt universal motor that plugs into any light socket.

BETTER SPONGE RUBBER

N EWEST adjunct to comfort is foamed rubber latex sponge used in upholstery, mattresses, and various cushion applications. This interesting material as produced consists of a hardened froth of rubber formed from latex, which is the milk of the rubber tree and primary source of all natural rubber. The process of manufacture begins with a concentrating operation to increase the ratio of rubber to water in the latex by passing it through a centrifugal similar to a cream separator. To the concentrated lates are added suffer and other compounds accessary to is subsceptent violentizations of a forming agent to aid of a forming agent to aid of a forming agent to aid the second of a forming agent to a compounded later as put in a bester similar to an egg bester or cream whipper which converts the hick laqued into a hight, airy froth. The forth is stabilized by the addition of a gelling agent and is then vilcanized in a mold immersed in hort water at approximately 20% degrees, Fahrenhert, for the length of more required in the particular compound to being used by several leading rubber manufacturers under hereas?

The principal application of foamed lates, sponge is in cubinon, mattresses, and up-bi-stery, but in addition it is finding important uses as a shock absorber and cushioning agent in industrial machines. This inwelled of making rubber sponge is much simpler than older processes which depend upon the generation of a gas in small bubbles within a doughty mass of rubber.— D H K

AROUND THE EARTH WITH A SINGLE POUND

W EIGHING 0 00000009246 of a pound per foot, the aluminum wire shown in our illustration compared with a human hau is not a freak or a museum piece, wire of

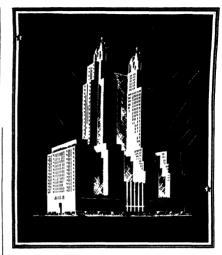

this diameter is used in string galvanometers for geophysical research and prospecting. The ware has a diameter of 1 '10,000th of an inch, and a single pound of aluminum could be drawn into 20,000 miles of such wire The cost, however, would be almost \$500,000 for that point.

SOAP BUBBLES FOR GROWN BOYS—AND FOR ENGINEERING

As a lad you probably blew on p bubbles, but as an adult you might like to try at again with a better soap solution, making bigger, more lasting bubbles possibly inflated with hydrogen to make them float or to explode when ignited, especially if you could do it ostensibly for the amusement of some youngers. In the Journal of Chemical Education, G. A. Cook of the well-known down the control of the control of

After much study of existing literature, including two excellent books that are available (C. V. Boys, "Soap Bubbles, their Colors and the Forces Which Mold Them," 1924;

A Partnership of SCIENCE and ART

If there is such a thing as a hotel being the expression and the essence of the finer aspects of the life of a city, surely it is no immodesty to claim that distinction for The Waldorf-Astoria.

Here, not only the art of living luxuriously, but the science of living wisely and efficiently, and therefore economically, come to fruition in such a totality of advantages as only art and science together could achieve.

Science is the source of its creature comforts, but what most endears it to the world is its knowledge and its practice of The Art of Home!

QUANTITIES LIMITED-ACT QUICKLY

For sale by SCIENTIFIC AMERICAN, 24 West 40th Street, New York, N. Y.

also A. S. C. Lawrence, "Soap Fillms," 1999, the author made numerous experiments which are described in his article, and finally reached the conclusion that a solution which can be prepared from materials readily available and in a minimum of time, and which will yield bubbles lasting from one to five munters in the open are thubbles in closed vessels lasted as long as 100 days), as made as follows.

An onne of powdered Castile soap is placed in a one-quart butte filled with distilled water (available at most drug stores and filling stations). The butte is shaken at micrasls until solution is complete, and allowed to stand for 24 hours or longer. The clearer part is then sphoned off and the rest herein a solution of giverner is added and thorough by mixed with it. The bottle must be stored in a dark place and at all times, kept well stoppered. When it is desired to use the solution, about 35 caps of it is poured out and airred with two or as a famine acid and is available at drug stores.

The article also describes the use of a new kind of soap called triethanolamine, for making flat soap films which last for several hours Such films are important in research on applane design and in the design of many kinds of machinery, because of an analogy between the tension, or stress, undergone by a structural member, such as a beam, and by a soap film stretched across specially shaped supports and strained by a blast of compressed air. Thus, the strain that would be experienced by certain parts of an air plane, for example, can be predicted without actually building the unit, and the best con struction for a given need can to some ex tent be determined beforehand. The article gives references to papers in which work of this kind is reported and explained.

SMOKED TURKEY PROCESS USES ULTRA-VIOLET

W 110 doesn't like smoked turkey? Who does, you retort, and a good retort it is, for few are aware that this delicacy can be had in America. Turkeys cured, then smoked and cooked at the same time are sought after by the gournets of this country, and the only source of supply, Pines bridge Farm (in Westchester County, New

GEARS

CHICAGO GEAR WORKS 769-773 W. Jackson Blvd., CHICAGO, III

A tuckey smoke-house

York) is kept busy shipping its product all over the country.

The process is secret, and begins with a special cure carried on in a refrigerated room From there the turkeys are taken to the smoke house for smoking and cooking There precise regulation of heat, ventilation, and smoke is e-sential. In a matter of minutes a whole houseful of fowl may be arretrievably ruined if the attendant relaxes his attention

For the last three years this farm has supplied smoked turkeys to the Waldorf-Astona. Colony Restaurant. The Stork Club, the steamship Queen Mary, the crack 20th Century Limited, and many other exclusive restaurants, night clubs, and establishments, and has filled orders for individuals whose names read like a page in Who's Who.

What is this secret process, and why cannot anyone smoke turkeys? First of all, the brine in which the turkeys must be cured after drawing them contains eleven herbs and spices, some very rare and obtainable only from a particular house in London specializing in them. During curing, and afterward until they are taken to the smoke houses, the turkeys are kept in a large refrigerator at a closely held temperature of 40 to 42 degrees, Fahrenheit, with the air circulated through the refrigerating units by powerful fans, and with all possibility of contamination by the mold of decay or the bacteria of disease eliminated by use of the Rentschler James Process, which uses ultraviolet sterilizing lamps. From this refrigerator, birds are taken as required to the smoke houses, where they are hung over a wood fire This fire cannot be made of just any wood, for the kind has an effect upon the taste of the meat. It has been found that apple wood is the best, and the farm's operator scours the nearby countryside for old apple orchards, which he buys and cuts into cordwood

ACETIC ACID IN PETROLEUM REFINING

DURING recent years numerous solvent processes have been introduced for the refining of petroleum. The latest of these, developed in India, uses glacial acetic acid as the solvent. By adding water to the acetic acid solution it can be given a solvent power varying at will. The principle of operation

of this refining method is to dissolve part of the oil, leaving the rest undissolved. In this way separations can be effected which are difficult, if not impossible, by distillation or other methods independent of solvents—D. H. K.

WHY SOME BIRDS

MOVE THEIR HEADS

THE vision of most bards is moneular, the visual fields of the two eyes being quite independent of each other. Monecular vision with two exes, each having a short facins, side angle lens, has the advantage of giving a sharp and distinct trainal image of everything within two large visual fields that has the disadvantage of reording two independent amone more remaining two independent amone major reording two independent amone major reording two independent amone images are made to be a sharp of the disadvantage of the control of the control

The disadvantage is overcome by the horizontal head movements of such brites as the doves, piggons, costs, and gallinutes and by the vertical licid movements of the abore brids. Such head movements provide a base line from which distances may be measured, and the blotting out of the image between the extremes of this base line, assuming a returnal lag, results in a sterioscopic effect.

Thus the birds, under the apparent physical handicap of monocular vision, in reality, as a resultant of the movements of the head, possess all the advantages of binocular vision, in addition to the advantages inherent in double monocular vision.

Although it is believed that the attainment of the advantages of binocular vision is an important factor in the head movements of birds, it is not assumed that it is the only factor, or that it explains its origin—Anstra H (lath, Zoologist at U. S. National Mayeum.

FIREPROOFING WITH

PAINT

BRITISII chemists have recently developed a paint to be applied to wooden structures to reduce the hazard of fire from meendary bombs should a war occur. The paint localizes the fire produced by the bombs and has proved successful in small scale tests—D. H. K.

DROP-IN COOLING UNIT

ROGINEERS of Frigidaire Division, General Motors Corporation, have developed a new "drop-in" milk-cooling unit which can be installed in any standard type of milk-cooling cabinet, it was announced recently.

The new unit consists of a cooling coil and motor driven water-circulating device enclosed in a cylindrical steel shell. The cooling coil is connected to and refrigerated by means of a Frigidaire compressor.

The unit is shipped from the factory as a complete assembly which may be readily installed in an old or new milk-cooling cabinet and plugged into a convenient electrical outlet.

Proper temperature in all parts of the mik cooler are assured by the circulator which keeps the water bath constantly circulating during the cooling operation. Cool-

Droppin cooling unit motor driven that can be installed in any standard type cabinet used for milk-cooling

ing to temperatures below 50 degrees as required by many states is also insured, thus retarding bacteria growth and eliminating spoilage and rejection losses.

The unit is completely automatic in operation, climinating the labor required by old style cooling systems. The new unit is available in two sizes for cooling two to six cans of milk per day it is ideal for the require-ments of the small dairy.

EFFICIENT COPPER-OXIDE RECTIFIERS

COPPER OXIDE rectifiers having a canow being economically used to supply direct current in an electrotyping operation Rectifiers of this type have been used for many years in various applications requiring relatively small amounts of electric power The present installation is the first in the electrotyping industry, and during approximately six months of operation has proved itself both efficient and economical. The initial cost of the copper-oxide rectifying system is approximately half that of a motorgenerator installation of the same capacity, and since no moving parts are involved it has no tendency to wear out. The alternating current as purchased is passed through a transformer to bring it down to the low voltage required and the current at low voltage is then rectified.-D H K.

FINDING METEORITES

SPECIMENS of 70 meteorites have been added to the collections of the Smithsonian Institution, at the nation's capital, during the past year, 62 of them representing new falls. This brings the Institution's total number of meteorites to nearly 700, or more than half of the known meteorites reported to have hit the earth. The largest specimen acquired last year weighs close to 90 pounds and the smallest only a few grams.

The Smithsonian is eager to obtain as many as possible, is actively engaged in building up a great collection of these meteorites for study, and encourages people to search for them. The students of meteorites to a large extent depend upon the chance discovery of them by the people throughout the country, and to stimulate the search, the Smithsonian rewards the finder.

Meteorites are all very heavy for their size, and much heavier than the average rock on this earth, the reason being that they sometimes consist of an alloy of iron and nickel, usually over 90 percent iron. When the stony

TECH EDITORIAL SERVICE 26 West 40th Street, New York, N. Y. hon papers. Due to the fact that the carbon and the master-copy sheet in one unit is ready for use when taken from the box, the operator finds no necessity for touching the hectograph sheet itself, thus avoiding all possibility of staming the fingers or clothing

FABRICATING Non-Ferrous Metals

A NEW process which makes possible precision shaping of non-ferrous metal- and plastics, in sizes and designs which form crity could not be produced, has recently been mitroduced on the market. It literally begins where methods of extruding or rolling end, for it produces, in any length rods, designs to complicated and sizes too small to be set.

cured by any other known method. Undereuts, which hitherto have frequently proced an neurmountable obstacle in construction, are entirely solved by this method. Precision, too, can be held down to .002 inch, and even less, if required.

The accuracy and multitudinuss designs which are possible by this new process can be quickly produced, at low cost. Secontists, organices, and designers can, by this process, without probabitive cost of dies or milling work, unmediately have almost any concessable shape made to order in the shortest

In the automotive field alone, many designs which have hitherto defied the skill of productive and tool experts, can now be manufactured with surprising facility. - (F. Greeves Carpenter

Answers to Problems

The answers to the problems proposed on page 219 are as follows:

Crossed ladders: 27.87 feet. Spheres: 0.74048 in either case, since the ratio is the same for balls of any diameter.

Barge: 4.660, 4.012, 5.166, 4.518 feet; pressure is 38.73 tons. Dog-rabbit I: 9½1 sec., 6.105 sec. Dog-rabbit II: 3.717 sec. 68° 36' 54" east of north.

HERE COMES TELEVISION!

(Continued from page 209)

climinate the event of going to the theater. Television, however, will probably make use of many films, either shorts or films made especially for television.

I am not emisently qualified to speak on the subject of the television receivers that are seen to be marketed. I assume, as I have said, that they will be reliable. There will probably be both table and console models, mobodying several sizes of Kinescope—perhaps five-sinch, seven-inch, and twelve-inch tubes. The largest of these gives an image approximately 7½ by 10 inches in size. Almost all of the models will also reproduce the sound associated with the picture; but it may be that the less expensive models will require the addition of some form of ultrasient wave adapter to the ratio frectiver alsient wave adapter to the ratio frectiver al-

CAN MAN REACH BEYOND THE VEIL?

On the Edge of Eternity

NO CLOSE and yet so far from S the source of all is man. Are we allowed but a fleeting glance at the universe-just a conscious interim on the stage of life-a brief look at the setting, the stage, and our fellow players2 Must each minute be lived regardless of what it affords, or can life be an intelligent choice -- a time well used to gain a desired end? Not alone in the vapors of test tubes, or the misty yords of the telescope. will man find the answer to the riddle of life and that course of living which brings mastery of self and happiness, but in the depths of his own being

The surges of self which the emotions well up within you, the flashes of intuition which break through your conseiousness in spite of superfluous increasts are the signs which point a way to contact with infinity—the primary cause of all. Certainly you are not—nor are men generally—averse to brillance of mind, to creative ideas which make for accomplishment, and have their worldly counterpart in demands for your personal

services and success in any enterprise

Therefore, let the Roserucians (not a religious organization), and age-old, world-wide frater-nity, reveal to you the simple methods used by the sages and master thinkers of yore for shaping the elements of your environment into a world of personal achievement. This knowledge goes beyond mere faith or belief It is the ageless science of life, which has accounted for most of the world's greatest thinkers and doern.

ACCEPT THIS GIFT BOOK

The Roserucians invite you, if you are not merely content to drift with the times, to use the coupon below and secure the fascinating book, "The Secret Heritage"—without cost or obligation—which tells how you may receive these forceful and eternal truths which make for better living

AN APE

may be a mathematician when he can count to two! Count: units, tens, myriads and millions and be a mighty mind among mathematical apes!

Count all the numbers from tithes to trillions and you have counted only numbers of *one* dimension. Among men your mathematics counts but one?

For those who now count in one dimension and would count in two or three we offer

SECOND AND THIRD DIMENSIONS OF ALGEBRA

by Robert A Philip Price two dollars

THE MONOGRAPHIC PRESS

sound to accompany the television image It will seem to many that the largest size television image now practically obtainable will still be far too small for home entertainment needs. A comparison will be made between television's images and those of the motion picture. The habit of viewing scenes on a large size movie screen will probably prejudice many persons against television's present images. I believe, however, that most persons will be surprised at the amount of interesting detail that can be portrayed in the larger size television images. It must be remembered that the television image should be seen at the proper distance. At a distance of five feet the eye subtends the same angle at the television serien that it does from the tear row of the average motion picture theater. Experiment on devices for producing larger images by projection methods is un der way The present projection tube, with its associated apparatus, is still too complicated and cumbersome for home use

There will also be many persons inclined to "wart until they perfect this thing" before they consider the purchas of a receiver. This will feel that there will be rapid obsolescence in the receivers, that perhapsiandards will change in a short time and render the receiver that cost perhaps several hundred dollars a usel ics spece of furniture.

The factor of obsolvemen is cretain to count rather heavily. What assurance can be give against rapid obsolvemen? Tele sixon has been long in developing and has progressed, through an evolution that has progressed through an evolution that has see many methods and standards treat and distanted. If a single set is to receive the programs of all stations within a given ser see area, uniform standards must be set up for all transmitters andards must be set up for all transmitters.

A subcommittee on standards of the Radio Manufacturers Association has tussled for years with this problem. The British, in 1936, established a public television service in the London area, operated by the British Broadcasting Corporation and financed out of receiving set licenses levied on every radio set We in the United States have fol lowed the success of the British standards, adopted those which proved their value and rejected those which to us seemed inferior to those proposed and tested here. For more than two years the NBC station in New York has been a proving ground for many of these standards Now the body of standards pro posed for an American public service in tele vision has been adopted by the radio in dustry and recommended to the Federal Communications Commission They repre sent an advance over those prevailing in

Britan.

Here, I believe, lies the answer to those who feel that we are starting television broadcasting without adequate the start of the proportion of the doption of the start was and ards was not precupitate. For technical reasons, if for no other, American television has been delayed to assure the doption of the hest possible group of transmission standards. They were arrived at without prejudice to anybody's claims and I feel certain they offer the enduring basis for American television I feel certain, too, that they will not soon be modified and that receivers based upon them will give years of satisfactory service to the first buyers.

But, after all, the best way to judge television is to see and hear what it offers. Take a look at the images when you can! I think you will be as enthusiastic as we are.

THE TEXTURE MATRIX

BOON to the miniature worker and A BOON to the ministure worker and the fine grain problem, and offering an opportunity to all photographers to in troduce surface texture effects not inherent in the printing paper, the so-called texture screens are finding a wide public William Mortenson, with his steel engraving texture matrix, is probably responsible for bringing the method into the vogue it enjoys today That his lead has been followed by others is indicative of a growing interest among amateurs desirous of improving the surface appearance of their prints

Recently, we had an opportunity to try out the latest variation on the texture matrix theme, namely, the Dia-Matrix Screens, which are available in three textures. Tap estry Bromoil, and Charcoal Of the three we personally lean strongly toward the last as offering the most for ones money in the final appearance of the print, but that will doubtless be disputed by other users of the screens, who may prefer the other

The sercons, which are available either in

"Straight" enlargement

the 8- by 10-inch size or the most common salon size, 11 by 14 inches, are individually hand-made and spotted. Like photographic film or paper, the screens have an emulsion side, on which the texture markings have been applied, and a plain, untreated side. In use, the emulsion side of the screen is placed in contact with the emulsion side of the sensitized paper on which the print is to be made, the uncoated side of the screen facing the negative image projected

Bromoil

from an enlarger. Closest contact is achieved from an interger, closest contact is achieved through the use of a regular printing frame, but in her of this a sheet of glass may be employed. The printing frame is to be preferred for the obvious reason that unless there is absolute contact between screen and paper, uneven impression will be the disappointing result.

There is no hard and fast rule as to what constitutes the correct printing depth when employing these screens, for the degree of texture imprinted on the sensitized paper

Tapestry

varies with the subject, the amount of image detail one desires to retain, the general effect aimed at, and other factors. For large heads, for example, a longer printing time may be allowed and a consequently clearer, that is, darker, impression of the texture achieved, than might be the goal where a landscape is involved. In exposing the examples shown on these pages, printing time was three and one half times that required for the "straight" enlargement. And this seemed to be about right for the subject. Also, different paper surfaces will make for dif ferences in the comparative effects achieved with these screens. In general, it may be assumed that semi-matt and matt papers are the most suitable.

Bosides the surface of the paper and the length of the exposure, the degree of tex-ture may also be controlled by the type of developer used. A brilliant negative is recommended, though it is held that any good negative, whether contrasty or soft, will yield satisfactory results, employing a contrasty print developer and a contrasty paper for the former, and a soft paper and soft print developer for the soft negative,

The screen markings being naturally most evident in the shadows, one must be sure to print long enough to imprint the texture in the brightest highlights. The beginner in this work must guard against a certain umidity in this regard for the texture unpression must inevitably call for a darker print than would result without the use of the screen.

Owing to the necessary coarseness of the screen impression, which is due to its hand-worked appearance, opportunity is afforded for sketching in little changes here and there. For this purpose an ordinary lead pencil may be employed.

FOUNTAIN PEN FLASHLIGHT

IT'S not sold as a photographic accessory but there's nothing handier for some darkroom purposes than the inexpensive which you probably have seen in the stores. Immediately coming to mind is its use for "flashing in" dark areas in a print during enlarging. Those light or meaningless areas that interfere with the effective presentation of the main subject in some prints are thus conveniently snuffed out without affecting other portions of the projected image. The clip with which these devices are equipped makes it possible to have the flashlight always handy as it can be carried in the pocket alongside one's fountain pen

FLASH SYNCHRONIZATION TESTED

MAKING possible a regular program of checking the synchronizing outfit, a new testing device for the purpose of check ing the relative timing of a camera shutter with the flash of a flashbulb has been made available by the General Electric Company in the G E, Synchrograph The Synchrograph consists of a case with an aperture at each end, a film-holding chamber taking 4-by 5 film, a rotor which is twirled by means of a knob, and two simple optical systems by which light entering at the apertures is directed to the film through slits near the respective ends of the rotor. The device may be used in any ordinarily lighted room

In use, a Photoflood bulb is placed inmediately behind the ground-glass focusing screen, the lens board of the camera is racked out so as to position the lens close to one aperture of the Synchrograph, and a Photoflash lamp is placed in the other socket, the cord being plugged into the socket of the synchronizer. The Photoflash lamp is placed in line with the other aperture of the synchrograph, and a shot is made

Development and fixing of the film in the usual way will reveal one of three conditions. Shutter opens at peak of flash (cor reet synchronization), shutter opens ahead of peak (thin or blank negative, synchron izer needs adjustment to delay opening of shutter), shutter operates later than the best part of the flash (should be adjusted to open sooner).

SMALL STOPS AND DEFINITION

THE widely held notion that the smaller the stop the greater the definition afforded by a lens is disputed by llford, Ltd., of England, who support their stand with the accompanying photomicrographs which are from very fine line printed originals taken on Thin Film Half Tone Plates. The first set of lines shows the definition at 1/20; the second set, the result when stopping down to f. 40, and the third set, the result

at stop //80. While the difference between 1/20 and 1/40 may not be so clear in the scaled-down reproduction shown here, it is very apparent as between f/20 and f/80. The conclusion is that the relatively large stop of //20 gives better definition than f/40 and much better than 1/80.

So You Want to Take BETTER PICTURES

By A. P. PECK
Associate I ditor
Scientific American

THE book you need to get the best results in photography

QUESTIONS that you want answered, things that puzzle you, all are explained in simple, straight-forward style, free from technicalities. Written for those who have their developing and printing done by the photo shops.

SOME of the phases of photography that are covered. Your Camera and How It Works; Lens Speeds and What They Mean; Exposure; Lightung Indoors and Out; Portraits; Landscapes; Tricks With Your Camera; Action Pictures; Your Pictures Can Be Enlarged; Equipment; and many others.

"SO YOU WANT TO TAKE BETTER PICTURES"

Over 200 Pages
Dozens of Illustrations
Board Covers

SCIENTIFIC AMERICAN
24 W. 40th St., New York, N. Y.

"This applies to all types of lenses," say the Hlard people, "and arises from the diffraction of light which occurs at the edges of the step and has nothing to do with the photographic material employed. With a small aperture there is greater diffraction which causes light to be scattered beyond the edge of the mage and so produces the ill defined edges sometimes found in practices.

PHOTOGRAPHING WINDOWS

F you should even have occasion to photographs deplay whether for love on money, here's, a try we pucked up to those you will be trouble with window pictures is that of reflections from across, the street, as you doubtless Roow These two photographers were wartening overame the difficulty by stretching behind the camera a long sheet of black cloth about three times the width of the window being photographed. Operation of the camera shutter was by "remote control" employing a long cable-right.

BLUE TONING OF PRINTS

A WIDELY used formula for the blue toning of prints was recently published in the Zerss Magazine. The formula, for use only with chloride and chlorobromide papers, follows.

Gold Chloride Blue Toning Formula

Solution A	250 cc	8 oz
Cold Chlorid	1 gram	15 gr
Solution B	250 cc	8 oz
Citri Acid	3 gram	50 gr

Solution (

Thoraxhamid (Thourna) 3 grams 50g These are stoke shittons. A working solution to tone three 11- by 14-inch prints consists of one ounce of each of the above solutions plus ten ounces of water, the work ing bath heing noed at 65 to 70 degrees. Toung commences in five minutes to a half to two hours. Aguste during insing for even action of the bath and wash afterward for a half hour.

The prints must be washed well after faring and before tuning and again after ton log; prints must be fixed in a plain or acid fixing bath without any hardening agent, and prints must be oxposed and developed as to be lighter and have less contrast than is desired after they are blue-toned. Also, different tone depths will be obtained with different paper developers.

BACKGROUND ON HOOKS

O'R srx-by-vax-foot background (stretch of on a wood frame), supported by projecting woods "Lin" at the sides, had been standing on the floor of our studio for a long time when a swinting friend objected on the strength of the standing on the floor of our studio for the strength of the standing on the floor of the standing on the standing of the st

ground from the walls, with a pair of hooks at each soft. On all hat full-lighty pictures, the background was high enough, being separant from the floor by mly a few inches. For full-lighture portrait, or similar short, the background could easily be lifted off the hooks and stood on the floor at a slight claim, with the wall as a support That we thought the idea a swell one is attested by the accompanying photographic proof.

Panatomic-X in Larger Sizes

II THERTO available only in the 35-mm regative size, Panatemie-X may now be had in a wide range of roll film and film-pack size. The manufacturer recommends the new film as an all-around remilision, including the requirements of copying photographs, the properties of productions and documents, etchnical photography, and salon and exhibition work.

FERROTYPE PLATES

THIUMBING throught the current issue of Studio Light, the Lastman Kodak Company's house organ for professionals, we found a suggestion concerning ferrotype plates that should help the annatu or as well. It will be real news to many that ferrotype plates, which are frequently washed and upon which wet prints are placed to dry, may actually be damaged by water.

"Some enamels," says the writer, "are totally impersons to water, but the particular cannel used for ferrotype plates is not After these plates have been repeatedly allowed to stand in water for consist rable lengths of time some of the mosture penetrates the enamel, rusts the metal beneath, and causes small blisters and uneven surface roughness. This, of course, runs the plates."

The advice is, first, not to allow the plates to soak in water for hours at a time, and, second, never to set them away to dry with drops of water on them

ADD PHOTOGRAPHY

INFLUENCE

WE don't know where it is all going to wend up—and who cares?—but it seems that photography is still poking its nose into activities outside its aphere. A Fifth Arenne store, for example, was, at the time of this writing, dramatizing, newspaper-lieudline style, its offerings of women's attempt, and using press cameras to put the story over. In each of a half done or more windows was a Speed Craphic camera, with synchronizing flashgom attached—kalart, Ab.

 Kodak 35's offer new high values in inexpensive miniature cameras. Fast lenses, precision shutters, eyelevel finders, finger-tip focusing, automatic exposure counter, filmcentering and locking device.

All three models load with Kodachrome Film for full-color transparencies, as well as a variety of Kodak Films for pictures in black-and-white. At your dealer's . . . Eastman Kodak Company, Rochester, N. Y.

d free booklet, How to Make

bey, Mendelsohn (playing no favorites, you see)—and an 8- by 10-inch plate-holder on which the appropriate advertising legend was written in chalk—or was it white ink? Attracted plenty of attention, too.

Another non-photographic activity that in cluded photography, nevertheless, was that annual National Sportsmen's Show at the Grand Central Palace, where a candid camera contest was held in connection with the program. That helped, too

ARGE empty spaces in the home can be

FOR LARGE WALL SPACES

beautifully utilized for hanging your best photographs by constructing a more or less permanent "salon" wall. Purchase a sufficient length of monk's (or friar's) cloth, which comes 50 inches wide, to cover the area in question. You may, of course, have your "salon" any width or length you desire or your facilities can accommodate Next purchase some molding of plain design and have it cut and mitred to fit the two long sides and the two short sides of the "salon." Tack the cloth on to the wall, driving the tacks as close to the edge of the cloth as possible, pulling the cloth taut, this way and that until the cloth is attached to the wall without winkles and with the squares in the cloth running vertically and horizontally --not askew. When this has been done to your satisfaction, you are ready to cover up the somewhat unsightly edges with the molding The molding should be sanded down and then treated to a coating of linseed oil. After it is dry, tack the molding in place. This will cover up the edges of the cloth and dress up the "salon" considerably. The linserd oil treatment will eventually cause the molding to turn a golden brown, which will give it a more pleasing appearance than some paint colors.

After the "salon" is complete, you have an area of display space of a certuin length and a certain depth Allowing generous, spacing above and below as well as between picture-decided on the hanging arrangement for your pictures, which should, of course, be mounted, preferably on 16- by 20 inch mounts Drive in picture books at the 14 quired places and hang your pictures.

An arrangement such as this is probably ment suitable in the basement playroom, in the den, the attic, possibly the spare garage—if any—which could very reasonably be turned into a sort of studio, if you felt on inclined. At any rate, it's an idea, and maybe you can add your own notions to bring the scheme nearer to the requirements of your own facilities.

KALART CONTEST

WINNERS

Announcing that the third annual contest will be inaugurated this summer, the Kalart Company officials comment on the second contest as follows:

"In analyzing synchro-sunlight pictures

Profitable Photography with the Miniature Camera

By Edwin C Buxbaum, ARP.S.

DESIDES having a considerable amount of fun with the minitatue camera, making trick "abots," art photographs, and the hek, you can also use; if for special paying work. This little paperper-bound booklet of 72 pages tells not only how to make interesting photographs that are salable to news agencies or magazines but also gives many clues to the very large number of types of photographs that can be sold. For those who wish to mik profit with pleasure this booklet should prove most helpful.—31.10 postpatid.

Second pure-Synchro-Sunlight

for the second contest it was found that a great advance has been made in the quality of the pictures submitted. Photographers are beginning to learn how to use the synchronized flash in their daylight photography The majority of photographs covered subjects and scenes related to the immediate family life Naturally, the most interesting subjects were those of babies, children, and pets. These synchro-sunlight photographs predominated in the contest and there were many fine example.

THE ZEISS ANNUAL SHOW

M ORE pictures are telling stories without benefit of caption or title than ever before, according to the findings of the commatter in charge of the Fifth Annual Zeiss Ikon Photographic Exhibition, which opened at the offices of Carl Zerss, Inc., in New York recently and is now on tour around the country. "It is apparent from a survey of this exhibition," say the committee, "that the present-day photographer, while retaining the qualities of spontancity and aliveness to human interest which characterized the old 'candid' shots with all their freshness, is now combining these qualities with pictorial and technical excellence. Portratture is informal. but has the qualities that make for good painting or good graphic art of any type. It is also noteworthy that more pictures tell a story without a caption or title necessary Like a good cartoon, the essentials of the drama are all there within the confines of the picture.

"Several years ago," the committee con-tinues, "a survey of photographs such as this showed an interest in candid camera shots which tended to take the subject off-guard,

possibly in an embarrassing moment. The | TROOKS photographer was alive to the human interest and the photograph showed spontaneity. The trend then went definitely away from these so-called 'candid' shots toward the pictorial, stressing composition and pictorial excellence even in action shots. Cropping a photograph to bring out the pictorial values became an important part of the work."

This year's exhibition differs from previous ones, in that it is limited to 300 prints. of which 200 are in an Invitation Section and 100 prints, as we have previously noted in this department, are the result of a nationwide contest.

The selected prints were picked from a total of more than 4000 entries, including photographs both from amateurs and professionals throughout the United States.

Included in the Invitation Section are prints by Adolf Fassbender, F.R.P.S., M. U. Wallach, Helen Thompson Farrell, M. U. Wallach, Helen Thompson Farreil,
Margaret Bourke-White, Dever Timmons,
A.R.P.S., F.R.S.A., J. Ghislain Lootene,

51 MOVIE CAMERAS

THE motion picture cameras being man-ufactured, sold, and used both in this country and abroad, now number 51, according to a survey just completed by Beshee Products Corporation, makers of amateur movie accessories These cameras include 8, 16 and 9.5-mm frame sizes, with electric and clockwork motor drives

ENLARGER HELMETS

NO need to stress the importance of keeping dust away from the enlarger, particularly the one employed to project miniature negatives. It is rather difficult, sometimes, to keep the enlarger as free of

Protection from dust

dust as we would like, so it is with something of welcome relief that many workers have seen the advent of the so-called enlarger seen the advent of the so-casted entarger "helmet," a simple oil-skin pillow-case-like bag, with strings. The bag, or "helmet," is merely pulled over the enlarger and the strings drawn together and tied. One such device is shown in the illustration

Amateur Photographers

New Ways in Photography, by Jacob Deschin. Eminently practical from every point of view, this new book contains nothing of theory and nothing that the advanced amateus photographer will not find valuable in one way or another. It covers the whole range of amateur photography, whole range of amateur photography, discussing such things as trick pho-tography, photomurals, retouching, infra-red, and a number of other sub-divisions that will not be found elsewhere in as clear and concise a man

INFRA-RED PHOTOGRAPHY, by 5. O. INFIGURE PHOTOGRAPHY, BY 5. U. Rawlings, A treatise on the use of photographic plates and films sensitive to infra-red. Exposure and processing are fully covered; formulas are given for sensitizing, \$165.

UNIVERSAL PHOTO ALMANAC AND MAR-KET GUIDE. How, when and what to photograph in order to make money with your camera; where to sell different types of prints, \$1.00.

CAMERA Lenses, by Arthur W. Lockett. Explains simply and clearly, yet with scientific accuracy, all the underlying principles of lenses. \$1.10.

CHAMPLIN ON FINE GRAIN, by Harry Champlin, A complete hand-book on the entire subject of fine grain, including formulas and how pound and use them. \$1.90.

PHOTOGRAPHIC HINTS AND GADGETS, by Fraprie and Jordan. How to make all kinds of photographic accessories; all kinds of photographic accessories; from film clips to cameras to light-ing equipment, and so on; 250 articles and nearly 500 illustrations. \$3.70.

ELEMENTARY PHOTOGRAPHY, by Neb-lette, Brehm, and Priest. You can learn much of the fundamentale of photography from this little book even though you have little or no knowledge of physics and chemistry.

PHOTOGRAPHIC ENLARGING, by Frank-lin I. Jordan, F. R. P. S. One of the most interesting and authentic books most interesting and authentic books on enlarging, Its 224 pages cover every phase of the subject and 75 illustrations, many of them salon-dinners, show the value of correct technique. \$3.70.

PORTRAIT PHOTOGRAPHY, by H. Wil-liams. Fundamental principles of composition and lighting, paving the way to satisfactory results in this particular branch of photography. 34.45.

7 inches. Standard equipment anastigmat lens No. 101, which makes 5 by 7-inch prints from full vest pocker (1% by 21/2 inches) negatives, 31/2 by 5 prints from half vest pocket and Bantam size, and 21/2 by 31/2 prints from double-

IINIVERSAL PHOTO ALMANAC AND MARKET CHIDE 1939

AMATEUR photographers who feel that they should be able to make money with their camcras will find in this book many hints that will be of value. A series of articles tells what, when, and how to photograph, how to sell your photographs profitably, how to handle your equipment, what picture journalism consists of and how to make contacts with editors, and many other things that the would-be photo journalist will want to know. A pictorial section presents some of the work of this country's foremost photographers; a large formulary gives in compact form most of the standard formulas. The market guide section tells who purchases what kind of photographs, approximately the price paid, and gives other pertinent data regarding hundreds of publications that are in the market for photo-

Eighth Edition Revised-Up-To-Date 50 Cents, Postpaid

SCIENTIFIC AMERICAN

24 West 40th Street New York City

JACOB DESCHIN, conductor of our "Camera Angles" department, will answer in these columns questions of general interest to amateur photographers If an answer is desired by mail, enclose a stamped, addressed envelope. Queries should be specific, but Mr. Deschin cannot undertake to draw comparisons between manufactured products nor to advise on the purchase of equipment or materials -- The Editor

Q. Is there a quick method of drying a roll of 6 by 6-cm film so that enlargements may be made as soon as possible after washing of the negatives has been completed?—L. M.

A. A "warm-breeze" fan will do the trick Hang up the film strip, remove surplus water carefully from both sides either with a viscose sponge or cotton, and allow the nega-tives to dry "normally" for several minutes. Then plug in your electric fan and direct the heat toward the film strip, taking the precaution of providing a reasonable distance between fan and negative strip so that drying will be gradual and the heat will reach the strip fairly evenly

O. Do photo chemicals, in general, deteriorate when kept dry and in the container? For example: I have a pound of carbonate I bought six months ago and it is only half gone. Is it likely to harm the quality of either negatives or prints when I use the last of it, say, six months from now? How about developing agents, such as metol and hydrochinon? An ounce lasts me a half year.-A. W.

A Provided you observe the precaution of keeping the chemicals absolutely dry, with secure covers and stoppers on cans or bottles, chemicals in the dry state will last a long time Deterioration, through oxidation, begins really to set in seriously when the dry chemicals are converted into solution

Q. I am considering buying a Ger man-make camera. My brother is and will be in Germany for some time and I have thought of sending him money so that he could get the camera there. Could you please tell me what duty I might have to pay if he keeps the camera there and uses it to supplement his own camera and then brings it to me when he comes? Or, as another possibility, what arrangements would have to be made if he were to send it to me direct?--J. B. P.

A In either event, it would be necessary for him, when he brings the camera into this country, or for you, if it were shipped to you, to pay a duty of 20 percent on about half the American list price of the camera, or

the price paul for the camera abroad, whichever is the higher figure. Were a camera involved in which the lens had a higher value than the camera, a duty of 45 percent would be assessed In addition, it might be necessary to obtain special permission from the manufacturer's office in this country for the privilege of importing the camera. In general, it is not advisable for individuals to bring cameras into the country. The importer here cannot be expected to feel a responsibility for a camera he had no hand in importing and from which he gained no profit Therefore, should anything go wrong within the year covered by the guarantee the individual importer of a camera would have no redress from the importer or, as the term is loosely used, the "agent" in this country In addition, the camera purchased abroad will have the Continental type of tripod bushing requiring the use of a hushing adapter to bring the size down to the American standard. And, of course, the focusing scale will be marked in meters, not in fact

Q. I am enclosing a pencil sketch showing the general outline of an en-larger which I am planning to build. I have an anastigmat lens f/5.4 salvaged from an old camera, and it is this lens which I propose to use in the enlarger-I would appreciate it if you would briefly describe the essential features and

requirements of the enlarger—P. G. H.

A. Answering your questions in the or-der indicated by the sketch, a 100-watt lamp of the opal enlarging type will provide a satisfactory light source; the lamp should be located opposite the center of the condensers and mounted on a movable rod to facilitate altering the distance between lamp and condensers. (Your sketch shows one condenser; to utilize the full value of the condenser type of illumination, two must be used) The illumination should, of course, be sufficient to cover the entire area of the size negative being enlarged. The condensers or a little larger than the diagonal of the 31/4 by 51/2-inch negative you are planning to enlarge. The condensers should be mounted convex side toward each other and flat side outward. The negative holder should be

located as closely as possible to the con-denser, and should be provided with a mask, with an opening just large enough to accommodate the negative being enlarged You do not mention the focal length of your lens so we cannot give an accurate reply to your question concerning the ditance from the negative to the lens However, assuming your lens has a focal length of six inches and a two-times enlargement is the smallest you will require, the distance from negative to lens should be nine inches. If the focal length of your lens is slightly greater, allow for a greater extension, per haps as much as 1/2 to 1/4 of an inch For greater enlargements than two times, this negative-lens separation will be t portionately shortened as the enlarger belws is raised. For a six times enlargement, for example, this separation, under the circumstances, will be only 7 inches.

Q. 1 have a 12-inch 8-hy-10 rapid rectilinear (//8) lens. Am planning to remove one glass disk (either front or back) to increase the focus to 24 inches, and attach to 24 by 2-yi-inch camera. Kindly advise me what your opinion is on this subject. Would you rather recommend a telephoto lens, say about 7 or 8-inch focal length;—P. W. T.

A. While this is rather unorthodox procedure, there is no reason why you should not be able to use the big lens on the small camera. However, you understand, of course, that you will have to provide the lens with a tube so it will be separated by 24 inches from the film plane Furthermore, since one element of the rapid rectilinear will admit only about one-fourth the illumination of the complete lens, your f value will be cut to 1/16 at full aperture You may, of course, retain the f/8 speed by using a 12-inch tube and employing the complete lens Concerning the purchase of a telephoto lens of 7 or 8-inch focal length, one of the principal advantages is the likelihood of greater lens speed. Chiefly, the question must be answered by your own needs or desires what type of work do you wish to do; what distances do you wish to work from; how much of the subject do you wish or need to include on your negative? Other questions will occur as you study the subject more thoroughly

Q. Can you suggest a book which will help me to sell snapshots? I would like to know something definite about selling them. What size print to send in and whether one should sell negatives or just prints. Can you suggest place to send various types of pictures?— H. C.

A. H. Rossite Snyder has been putting out booklets on this subject for years and many anateurs owe there camera pin-money successed directly to his advice. The booklets may be seen in practically all photographic bookstores. "Photo Markets", by John P. Lyons, and the "Universal Photo Almanac and Market Guide" contain extensive hist of possible markets for photographs. Among the helpful books on the subject are: 'Making Anateur Photography Py", by E. J. Eackson, a practical news picture syndicate man; George W. Hesses'. "Camera Journaffun with the Miniature Camera"; and "Press Photography", busen C. Klizkid, a working press photography.

rapher. Answers to your several questions will be found fully discussed in these books. Generally speaking, for yournalistic purposes, 8 by Joinch gloosy prints are required, although 5 by 7-inch prints are also acceptable in most cases. Whether to sell only prints or the negative itself is a matter for individual decision, of course. In some cases, where exclusiveness is desired, as by a picture syndrest, the sale of the negative and granted. Convertly a high price should be obtained where the impattice is sold.

Q. A friend of mine recently advised me to purchase a panehromatic monotone viewing filter. He recommended the use of this before each exposure. Will you please tell me just what the good of this is, how it works, and the proper method of using "—F. A. C.

proper method of using T—F. A. C.

A. The pandromatic monotone viewing filter, of which a number are now on the market, is employed to indicate to the eye approximately how a scene looks to the "black and white" negative, that is, at it seed to interper color values in monotonia territor. Generally, the weign filter than the strength of the contract of the contrac

O. For some time I have been interested in preserving printed matter in the form of small negatives, a process commonly referred to as "microfilm." I would like to use a Retina 35-mm camera and some of the cheaper or 'positive" film stocks. I have tried several films but in each case got grain which I consider too large for the best results. I would appreciate very much any information that you would be able to give me on this problem .-- L. E. W.

A. A film now being generally employed for the purpose you have in mind is Agfa Reprolath. This is available in 35-mm perforated stock in minimum quantities of 100foot rolls. A special, extremely high contrast developing formula which must be used is packed with the film.

Q. I have in excellent condition my first camera, obtained in 1901, a 314 by 414 No. 3 Folding Pocket Kodak. Could you tell me what f value corresponds to each of the three stops (three round holes in a metal silde)?—W.

A. M. A. Very likely the f values of these stops are 1/11, 1/16 and 1/22. The best way to find out is to calculate the stops for yourself Learn the focal length of the lens by setting the lens at infinity and measuring the distance from the front of the lens to the plane of the film. Probably you will find this to be 514 inches or thereabouts. Now measure the diameter of the largest of the three round holes. Divide this into the focal length and the result is the / value of the particular round hale measured. If the hale measures 1/2 inch in diameter, the stop is approximately //11, the next smaller would then be f/16, and the smallest f/22.

Here is the latest streamlined additions to the reputate hore of boilins. Nor minimisters it is remarkably light and compact, yet is a precision instrument in every sense of the word Among its many features is a built in range finder—lens-synchronized and optically serfect operating on the spill-image principle All control parts are easily located and quickly adjusted for latest pictures in rapid unconstant in built in view finder is fully compensated for particular the properties of the prope

BURLEIGH BROOKS

.

A Monthly Department for the Amateur Telescope Maker Conducted by ALBERT G. INGALLS

GOOD as the reflecting telescope is, like we in Figure performance does not equal that of the refractor, though its images are more brilliantly illuminated and it is achieved the resons for this, Nozher J. Schell, 1019 Third Ave, Beaver Falls, Pa., believed the chief culpent to be diffraction effects from the cevital obstructions—the diagonal and the telescope of the control obstructions—the diagonal and the telescope of the control obstructions—the diagonal and the thresheld in the telescope of the difference of the discount of the telescope of the difference of the discount of the discount of the difference of the discount of the discount of the difference of the discount of the discount of the difference of the discount o

Figure 1. The off-side reflector

ambler one is introduced; assignation A hun half båden on page fils o'r ATMA' suggested to Schell the answer, tiling how the late Prof. W. H. Pekering experiment of to kill off evil effects of central obstruction in a reflector. Over the outer end of the telescope he placed a displicagin having a hole less than half dameter and far off side, near the edge, so that the light that passed though it entirely escaped the dagonal and spider. Even though the mrore area was thus very greatly reduced, the seeing at one; improved and the images appared like those given by refractors.

Schell repeated the experiment and found Prof Pickering's words time. The upshot was the design and construction of the off-side telescope shown in Figure 1, in Figure 2, and in principle in Figure 3. At first al looks about like any ordinary Newtonian reflector (except that it looks unusually trim) but—far from it! Study the upper part of Figure 3.

"The method decided upon," he write,
"was to make a mirror of a certain diameter,
but give it a figure the same as if it were
a section cut out of a larger mirror, and to
one side of the center. The image from such
a mirror would come to the same point as
if the imaginary large mirror were in use,
but it would be sufficiently to one side of
the section actually used to permit us to

view it direct, or else use a flat or even a secondary, without obstructing the path of

light to the nurror."

To make this mirror, which would not be paraboloidal but eccentre or lop sided, "art of your distributed around a consultation of the mirror, distributed around a consultation for mirror, distributed around a consultation against the mirror distributed around a consultation against the mirror distributed around a consultation against the mirror distributed around a consultation against the large size of the assembly. For this and other trassitis, considering, even if that there was a more interesting, even if a barder, way) it was deceded to figure the off-side mirror snaply.

"At the time," Schell continues, "I explained the scheme to Mr TG Beede of Youngstown, Ohio, who has had 45 years of experience in producing high gade suifaces and who has no equal, to my knowl edge, in this class of work Mr. Beede betame interested.

"As Figure 3 shows, the 10" mirror 1s a second of an imaginary mirror 25" in diameter and 75" in becal length-long enough to use at primary focus, yet short enough to apply a future 21 secondary to give 15 final focus—that of the usual refractor, if this were desired.

"From this point on the entire job is a grace credit to the ability and patience of Mr. Beide. The figuring job is not one to be recommended for beginners!" [As II A. Lover comments, "It is easy to do -on paper—but what a lot of aspirm one would need before he made one on glass! "—self."

Well, Brede made the off side or lopsided mirror, and the final result was, in Schell's words. Star images that were small planet like disks, with ring systems surrounding them more nearly of the theoriral kind than we have ever seen in any reflector. Also increased detail on the North and planets—for example, colors in Jupi and planets—for example, colors in Jupi centuation of an estimated 50 percent of the light in the central disk."

The tube used is 13½" in diameter, with a small flat 5" inside focus, the image being brought out at right angles to the tube. The murior is titled about 46"

Afterward it turned out that there was already an off-side mirror at Mt. Wilson and two at the McMath-Hulbert Observatory, Schell savears on "ATM" that he did not know any such mirror had ever been made, and, even if several had, Beede figured the peculiar mirror from scratch since he had no instructions not of his own gradual mak-

So far so good, but how did he do it? For that is what the reader has no doubt heen saking as he read the above. This question we put up to Schell and he came through with all he and Beede had, Here

"While this is written by myself, Mr. Beede has concurred in the figuring description, he and I having gone over the matter the last time I was up to see him." [Yourgethe

town 40 miles N W of Braver Falls, Beaver Falls 30 miles N W of Pittsburgh,-Ed.1

"The mirror was worked by hand, face up, on a fixed pedestal, throughout grinding, polishing and figuring. Yo machine work or mechanical controls whatever were used, although a mechanical control was tirted first and discarded, as it was found unsatisfac

"After himging the mirror to a truespherical surface, no further movement complicitly around the pedestal in the ordinary way was possible. The mirror was always placed on the pedestal support in the idea tical position with relation to the axis linduring the figuring, and a mental picture of the condition of the surface guided the apinfraction of the figuring tools.

The figuring tools were puch-coated in the usual manner. Their size was varied, but they were all sub-diameter tools, the diameters varying from ½ to ½ of mirror di ameter, as needed. No advantage was found in the use of tools of shape other than round, and their edges were not trimmed to a rosette, or smalar form

"Considerable difficulty was encountered in getting a proper understanding of the surface from the appearance under test (Fig. u.e.), bottom, and the effect of the application of the tools in correction. Mr. Beede found it a dissinct advantage to use an elaboration of the kinde edge, consisting of two kindeedges lang each other in the form of a narrow perpendicular alt by this mache out would be made for earlier direction.

Figure 2: The non-concentric mirror

"These mirrors, when placed in this position for testing, while apherical, show marked surgonisms with the greatest apparent bulge of the state of the parent bulge of the position of the parent bulge and bringing the remainder of the sururing consists of lowerings and the fixuring consists of lowerings and the fixturing the surgonization of the surface into collimation. Likewise, when tested with eveptices, while apherical, the returned pin-hole image of all would not be satisfactory here) shows a marked come, and as the figuring progresses, the come will shorten accordingly. If proper action is taking place in the figuring; otherwise the distortible of the image indicates improper polishing action. This type of test and the figuring to correct the surface is not unlike correcting large refractor objectives described many years ago by Alvan Clark where he stressed particularly the local correction necessary to round up such lenses, the local figuring being necessitated by differences in the re fracting power of one portion of a piece of glass compared with another portion; and is quite apart from the zonal correction having to do with spherical aberration ordinarily associated with surface conditions or shane of a lens. While we do not have thus

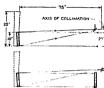

Figure 3 General plan of off-side telescope, and set-up for testing

trouble in nurrors, we have similar work in figuring an off-axis mirror.

"The figuring was found to require strokes following the varying radii, as indicated by the distances from the theoretical axis, great care being necessary literally to coax the surface down without getting too deep. Also it was found that, since the reduction involves undercutting the sphere, it was best to continue this action until the extreme outer edge area (r.e., side away from the axis) blended with the remainder of the sur face In other words, it was better not to attempt a combination action of lengthening the radius of the outer zones and shortening the inner ones.

"As previously stated, extreme care was necessary in orientation of the mirror relative to the axis-line when placing on the testing stand, as this would present an altered aspect, making it difficult to determine the state of correction.

"The final criterion of correction was the quality of the pinhole image as received at the testing position after the three reflections taking place in the set-up.

"The above is the result of experience in working three of these mirrors. The first was finished after running up several blind alleys and getting back out of them again. I feel that an experienced mirror worker will follow this description, but no doubt if he tries it, will use his own methods and get there just the same. So much depends on the individual, and his sense of touch and experience, in this hand work, that to lay down hard and fast rules is impossible. It is easier to do it than to tell how it is done. I think it was Ellison who once said that a man could read all the books on the subject and still might not have the ability to figure a good mirror."

Now that Schell and Beede have presented the working hints, who will undertake lop-sided mirrors? The surface is not an ordinary figure of revolution, and the work is irregular. Perhaps prudence is the better part of valor, if one is really a tyro.

THE BEGINNER'S

ROM day to day readers who have made telescopes from the instructions in the book "Amateur Telescope Making" kindly end in to this department descriptions and photographs of them and, while lack of space prevents publication of more than a very few, they are all closely studied here under a reading glass, and all details noted The one shown below struck this department as perhaps being one good solution of the beginner's problem of choosing a type of mounting for his first instrument. It is sumple to build, mexpensive, efficient, porta ble, yet it is neat and trim. This is one of two similar telescopes made by R. M. Wat rous. M D , 2027 Noyes St , Evanston, Ill . and Mrs. Watrous

Admittedly, this is not the telescope the average person has in mind to make, not claimate enough. To attain one's dream there are two ways. First, study the literature over and over, make numerous designs, evolve a complete one, build it Serond, study the literature, make a simple design like that below, build it, are it for a few

Mrs. Watrous and Watrous telescope

Detail of the simple mounting

weeks or months, and then, in the light of actual experience (which investibly brings to light numerous factors which no amount of mere study will reveal), design and make a telescope that will satisfy you. Those who choose the first course offen say later: "I don't think so well of this design of min as I thought I would, but I put to the actual properties of the previous properties of the preliminary telescope the Wattous type is offered as an excellent solution.

The axes are common pipe fittings. First a T with long mp and pipe nut is attached to the man leg of the triped through a hole ITMs. T also the other T shown, we horred out internally—about a 50 cent machine shop object to take the wost tub shafts. By an other arrangement, sometimes used, the axes turn on the threads already on the fittings, but succeeping through how to produce the state of the state of

The square tube of the telescope is made of straight ½2" stock, wood, two at each corner, edge nailed (better screwed) and is very rigid. Paint inside black. If near bright hights, enclose the lower 12" or so

Make main leg of tripod parallel the

Vary the details to suit your own taste Larger pipe fittings are suggested. Di Watrous himself mentions that the tele scope shakes a little too much in a breeze.

TELESCOPTICS ((ontinued from preceding page)

PEW amateurs attain the distinction of having the results of their work published in quite so "toney" a purely scenario profession of the port of the port of the strong the purely because the purely scenario profession of the their program of the recognition which the professional astronomers have given to Mr. H. A Lower the recognition which the professional astronomers have given to Mr. H. A Lower of San Diego by printing his marreluses photographs of the Milky Way, I am extremely enthusiastic," he adds, "about the efforts of the two Lowers, of Mr. Arthur DeVany, and of other pioneers in the construction and use of the Schmidt camera. These men have rendered a real service to satronomy and

have produced results of permanent value."

Ifarold Lower's textual contribution to the journal named (January number) consists of but half a page of very compact descriptive matter written in the scientist's traditional objective style, but the photo-

graphic contribution it so concisely describes consists of six full-page photographs in Orion, Cepheus, and elsewhere, taken by his father, Charles A Lower, in red light with the Lower Schmidt. These are repreduced on fine paper. "I call to your atten-"Dr Strave continues, "the conspicuous tion. little nebula shown on one plate. This nebula is shown only on the red photograph and is absent on the photographs secured with violet light. An inspection of our stand-ard photographs of the Milky Way by Pro-fessor Ross, Professor Barnard, and others shows that the object can be barely suspected on some of the best violet exposures, but it seems to have escaped previous detec-tion and is not listed in the NGC or IC. I am mentioning this case only because I think it should serve as an additional stimulus to our amateur astronomers.

Examination of the red-filter plate mentioned, and comparison with the no-filter plate of the same area, reveals a prominent object looking like a tuff of nebular matter on the one where there was nothing on the other. And so it looks to this departn which, however, lays no claim to knowledge of astronomy (telescope making is mechanics, not astronomy), as though the Lowers had discovered at least some kind of world, even if it is not southern California real estate. Moreover, they have themselves been discovered by the astronomers.

In the same number of The Astrophysical Journal there is a 14-page article on the tests of the 82" mirror recently figured by C. A R. Lundin, formerly of Alvan Clark and Sons, now of Warner and Swasey. for the McDonald Observatory, its author being Dr. J. S. Plaskett, Director of the Dominion Observatory, Canada, Dr. Plaskett is an expert among astronomers in testing large mirrors, having been called in by numerous institutions to test completed mirrors before their acceptance. The article shows in full detail how such mirrors are put over the numps, too bad that lack of space prevents reprinting it here, at least at present. (oncluding his tests Dr. Plaskett states. "The quality of the mirror proved to be unequalled by any mirror previously made or tisted," a completely categorical statement made possible by the fact that the mirror's maximum departure from perfection was nowhere more than seven tenths of one milbonth of an inch!

IN The Astrophysical Journal for Decem-ber, 1938, G. A. Mitchell of Pasadena has a five page illustrated article on "A Sim-plified Spectrohelioscope," describing the construction of a rotating-disk type of instrument. Readers of the Hale chapters on the spectrohelioscope in "ATM," will fully understand the significance. The design is such that all the mechanical work except one piece can be done with a breast drill, file, and a few taps. Muchell is an amateur telescope maker whose vocation is the manufacture of the Mitchell Motion Picture (amera, standard camera in the Hollywood studios

MOST normally constituted scientists en-joy reading scientific fiction of the H. G. Wells type, provided it is original and really clever. Hearing that Harold A. Lower had contributed to the January number of 4stounding Science-Fiction, your scribe visited the newsstand and picked up a copy to see how good the yarn would be. Disap-pointment! For the "yarn" turned out to be a straight descriptive article on stellar photography with Schmidts and other fast astronomical cameras, and at that, a pretty stiff technical one-and not estounding.

N The Journal of the Royal Astronomical Society of Canada, H. Boyd Brydon, of Victoria, B. C., recently published four articles on the design of small observatories, giving many detailed drawings of several types. These articles in separate form as a circular are now available for two bits, from the society named, at 198 College St. Toronto, Ont., Canada. Incidentally, Brydon has also published an article on "Two Inexpensive Drives for Small Telescopes," in the January number of the same journal, this also being two bits.

THE Amateur Astronomical Association of Des Moines is the name of a new organization of which C. O. Davis, Des Moines, Iowa (no local address furnished), is the secretary.

LEGAL HIGH-LIGHTS

Patent, Trade Mark, and Related Legal Proceedings That May Have a Direct Effect on Your Business

By ORSON D. MUNN, Litt.B., LL.B., Sc.D.

New York Ber
Edutor, Scientific American

LIBERTY

TEETOTALERS to the contrary notwith standing, ginger ale and beer are goods of the same descriptive properties, according to a recent decision of the Court of Customs and Patent Appeals.

In the case in question a brown filed a periton to cancel the trade mark of a ganger of a manufacturer consisting of a representation of the Statue of Liberty. The brewer that did adopted and used on here, prior to any use by the ganger-ale manufacturer, a trade mark consisting of a representation of the Statue of Liberty together with the word "therey". The Court found that the trade marks were deseptively similar to each other, and that here and ganger alle were goods of the same descriptive properties and accordingly ledd that the trade mark of the ging and manufacture should be cancelled

PADDY'S MARKET

PADDY'S Market was the colloquial name for an open-air market of peddlers and tetail vendors doing business on one of the public streets in New York City With the mevitable march of progress the market was forced to move from one location to another and finally was not permitted to do business on the public streets. The peddlers and vendors had formed an association un der the name "Paddy's Market Produce Dealers and Merchants Association, Inc. and when the market was no longer permitted to do business on the public streets the Association rented premises near its former outdoor location and the Association in turn subleased space to its members Thereafter several individuals engaged in business under the name of "The Original Paddy's Market" and the Association filed suit against the individuals to restrain them from using the name on the grounds that it amounted to unfair competition. On motion of the Association, an injunction was granted against the individuals restraining them from using the name "The Original Paddy's Market.

PRIDE VS. MODESTY

PROUD though we may be, our natural modesty places a certain restraint upon one announcement that once again Scientific American was one of the determining factors in a sait for patent infringement and as a result was instrumental in saving the United States Coverament from paying profits or demages in a suit for patent in for patent in the profits or demages in a suit for patent in the pate

A suit for infringement of a patent re-

lating to serial bombing was brought in the Court of Claims against the United States Government. The patent in soil related to a method of dropping bombs whereby the aircraft was pointed downwardly in a generally vertical direction and the bomb was dropped while the aircraft was in this position, thereby reducing to a minimum the horizontal moment which is ordinarily imparted to a bomb by an aircraft flying in a horizontal direction. It will be appreciated that in aiming bombs many different factors must be taken into consideration, one of which is the velocity of the plane when the plane is flying in a substantially horizontal direction. It was contended in behalf of the patentee that he had eliminated

"Fig. 7.—Making a dive toward the target. Leaning out wind-pressure, A would be the airman's point of release to hit the target while going 40 miles an hour. If, as shown also, he preferred to nose-dive to half-allitude, B would be his effective point for letting so his homb." Quoted from Scientific American Supplement, April 22, 1916

the factor of horizontal plane velocity, or

had, at least, reduced at to a manimum On behalf of the government it was contended that the method of bombing described in the patent had been described and published many years prior to the date of higher than the method and aupport of the contention a copy of the Scientific American Supplement of April 22, 1916 was introduced in evidence. The Scrientific American Supplement contained an article entitled "Scientific Bomb Dropping" and the scribe of the scientific American Contention of the Course of aim becomes easier, and effective work can be done without scientific instru-

ments; but rak from hostle fire becomes greater "Fig. 7 of the article referred to in the quotation is reproduced on this page isgeller with the descriptive explanation thereof, which appeared in the Screnific American Supplement in 1916. It will be noted that this figure shows both the method of releasing bombs while a plane is flying in a horizontal direction and while a plane is driving downwardly.

In view of this article and other publications referred to by the Court the invention described in the patent was held to be old and the patent was declared invalid.

IMPORTED PERFUMES

THE Circuit Court of Appeals for the Second Circuit recently rendered an opinion which will be far-reaching in regulating the practices of the perfume industry.

Perfume consists of a compound or concentrate including essential olls, flower essences, and animal matter or chemicals, which are blonded together in varying proportions in accordance with the formula of a ranus perfume. This perfume compound is a somewhat oily, heavy liquid which, while used occasionally commercially, is not saleable to the public until it has been diluted with alcohol. When the perfume is applied the alcohol evaporates and leaves the pertume compound or concentrate in minute

It has been the custom of leading perdumers to import the compound or concentrate into the United States and to dilute it with alcohol here. Perfumers adopted this practice because the concentrate or compound may be imported conaderably cheaper and the savings in customs duties are substantial. This product has been sold quite generally as an imported perfumer and merely with the naure of the perfumer and the words "Paris, France" or "Paris and New York."

The Federal Trade Commission has issued a number of complaints against leading perfumers charging that this practice constitutes mishranding under the Federal Trade Commission Act.

One importer appealed to the Creail Control Appeals from an order of the Federal Trade Commission directing that it descentine marketing perfuse so prepared as imported perfume. It was argued that the alcohol was merely a carrying agent and dibitant and that it had no effect on the finished product, that the several apertion for the product of the product.

The Court of Appeals held that the concentrated compound was not what the purchasing public normally understood as perfune, and that the addition of the alcohol (which constitutes from 80 to 95 percent of the finished product) was a manufacturing step necessary in order to sell the perfume to the public.

As a result of this decision it will be necessary for manufacturers who add alciohol or other diluting agent in the United States, to place a statement upon the containers in which the perfume is sold, to the effect that the perfume concentrate or compound was diluted with alcohol in the United States.

Are You~

putting your spare time to good advantage?

one of the many who are seeking a new field to en-ter?

meeking a means to save money wherever possible?

If you are, here is a practical solution to your problem.

HOPKINS' CYCLOPEDIA OF FORMULAS

Is the foundation for the beginning of a fascinating hobby; the groundwork on which to build a practical knowledge of useful chemical facts.

Is the foundation for hundreds of suggestions for those who are seeking salable articles which can be manufactured at home profitably on a small scale.

If you want to save money on wines and liquors; your dyes, inks, polishes, soaps, paints and varnishes. adhesives, antiseptics, bleaches, cosmetics, etc.

You can profitably make them from the 15000 formulas contained in the 1077 pages of

Thanks for the Laurels!

THANKS—a million of them—to a host of active Scientific American advertisers who so profitably cover the rich scientific and industrial market by consistently using the advertising col-

umns of this 94-year-old publication.

Our gratitude goes to all—for giving to Scientific American one of its truly greatest tributes, the honor of being acclaimed.

The Only magazine among All National publications to show a consistent gain in advertising linage during the past FIVE YEARS:

AND NOW IN 1939 gaining 5,969 lines over 1938

Surely this is an astounding record which proves that there is no "makebelieve" in the Scientific American market. "ITS READERS ARE LEADERS"—active industrialists, expert research heads—the men who are out in front in this ever-changing world of scientific development—the men who are responsible for BUYING advertised products.

Scientific American is a living—breathing—speaking—active SALES FORCE!

It is a powerful influence you should use consistently to sell your products. Greatest returns from your advertising expenditures will be yours when you "pound home" your selling message before this all-important high-purchasing power group.

A request will bring you the full facts about the rising tide of advertising opportunities in Scientific American. "ASK FOR BILLIONS".

24 West 40th Street

New York City

For MEN

who want to become independent in the NEXT TEN YEARS

N the Spring of 1949 two business men will be sitting in a mid-town restaurant. "I wonder what's going to happen next year," one of them will say, "My business is fine now-but the next few years are going to be hard ones, and we may as well face the facts."

The man across the table will laugh.

"That's just what they said back in 1939," he will answer. "Remember? People were looking ahead apprehensively-and see what happened! Since then there has been the greatest growth in our history-more business done, more fortunes made, than ever before. They've certainly been good years for me."

He will lean back in his chair with the easy confidence and poise that are the hallmark of real prosperity.

The older man will sit quiet a moment and then in a tone of infinite pathos:

"I wish I had those ten years back," he will say

· Today the interview quoted above is purely imaginary But be assured of this-it will come true. Right now, at this very hour, the business men of America are dividing themselves into two groups, represented by the two individuals whose words are quoted. A few years from now there will be ten thousand such luncheons and one of the men will say

"I've got what I wanted."

And the other will answer. "I wish I had those years back."

In which class are you putting yourself? The real difference between the two classes is this-one class of men hope vaguely to be independent sometime, the other class have convinced themselves

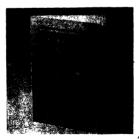

CONTRIBUTORS TO THE COURSE

Just a few of the husiness leaders who have contributed to the Institute training course are such prominent men as

I dward R Stettineus Jr Chairman of the Board U. S. Steel Corp Thomas J Watson Pres International Business Mach Corp Alfred P Sloan, Jr Chairman of the Board General Motors Corp

ING AHEAD IN BUSINESS" is an interesting, helpful booklet. It is yours for the asking. Send for it Musuire yourself by it. Look clearly, for a few moments into your next few years. Whether or not you will follow

that they can do it within the next few years. Do you believe this? Do you care enough about independence to give us a chance to prove it? Will you invest one single evening in reading a booklet that has put 400,000 men on the road to more rapid progress?

This booklet costs you nothing-and for a good reason. It is worth only what you make it worth. It explains how

> for more than thirty years it has been the privilege of the Alexander Hamilton Institute to help men shorten the path to success: to increase their earning power: to make them masters of the larger opportunities in business.

SCIENTIFIC AMERICAN

THE automobile, airplane, tractor, bus and truck engines of America not only have a tremendous appetite...but they are fussy in their tastes, too. They will deliver only the performance that the anti-knock quality of the gasoline you feed them permits.

That's why tetraethyl lead is, todia, almost as important as gasoline itself. Just a small quantity of this powerful, volatile liquid added to a gallon of gasoline improves its anti-knock value. It acts to prevent the annoying, power-wasting "knock" or "ping" that years ago threatened the development of the modern high-compression engine.

At the right you see what tetraethyl lead means in the performance of your automobile: TODAY EVERY CAR HAS 3 GRADES OF PERFORMANCE
Because there are different grades of gasoline sold
today, your car has different grades of performance,
depending on the gas you buy and the spark setting.
Use the chart below to help you make your choice:

Use the chart below to help you make your choice:

BEST PERFORMANCE—with gasoline marked

"Ethyl" on the pumpor globe. It is highest in antiknock and all-around quality. Contains enough

-êtracthyl lead so that your engine's apark can
be advanced closest to the point of maximum power
and economy without "knock" or "ping".

GOOD PERFORMANCE—with "regular" gasoline, which permits the spark to be considerably advanced without "knock" or "ping." Most "regular" gasolines now contain tetraethyl lead, as shown by the "Lead" signs on the pumps.

poor penromsamoE — with low-grade gasoline, poor in anti-knock quality. With low-grade gasoline in a modern car, the engine's spark must be retarded—which means loss of power and economy.

PLASTICS, PROBLEMS AND PROCESSES

By Dale E. Mansperger and Carson W. Pepper

THERE has long been a need for me, such a book a book with this the habbyst or experiments how to make all starts of objects from molded plastics. This volume, not only discusses completely the method of working such plastics, but also gives a large number of plans, carefully discussed in the control of the plans, carefully discussed in the control of the plans, carefully discussed in the control of the plans, and the plans, and the plans and discussed with careful size and the plans and discussed with careful size and the plans and the plant and the plans and the plant and the plans and the plans and the plant and the plans and the plans and the plant and the plant

CONSTRUCTIVE METALWORK

By James H. Evans

WE might say that this volume should be a companion price to the one mimidiately above. It also tells how to make mist attractive prices such as lamps, candicsitels, coal tongs, and such-practical things as solid ring rines carpenters¹ to sel gazes, and real-kettles, all in metal. We would chaicetize this a "must" book for all amorteum netal workers. (95 pages, 7½ by 10, will liberated) > 3.51 poeption 4.5. D. M.

RADIO TROUBLE SHOOTER S HANDBOOK

By Alfred A Ghirardi

PACKED into the pages of this large book, we act remembors amount of data which had not be the progresser, indoo service man as well as to those whose interest in accordance of the progresser, and the progresser in the materials approximate and repair. The materials approximate and repair The materials presented in 52 sections arranged from 231st models of radio receivers through studies, for common troubles in materials approximately and the properties of t

PRACTICAL SEISMOLOGY AND SEISMIC PROSPECTING

By I. D. Lect

Of the total content of this very practical book, five sixths are devoted to sensmology and one sixth to seismic prospecting.

We can supply our readers with any of the books reviewed in this department. Prices quoted include domestic postage. Foreign prices are necessarily higher due to increased shipping charges.

SCIENCE EXPERIENCES WITH INEXPENSIVE EQUIPMENT By Carleton John Lynde, Ph.D.

A COMPANION book to that small vol me "Science Experiences With Home Equipment" which has enjoyed a very large sale. This one deals with physical principles that when presided by the matter in the home savor of magic to the observer. A few camples are How to remove a boule cark without roughing it; Centrifugal force demonstrated with an egg beater; Lifting the constraint with an egg beater; Lifting the constraint with an egg beater; Lifting the state of the companion of the com

OUR POINT OF VIEW

Modern Alchemy

ARE American research chemists As asleep? Are their efforts pain of comparson with the efforts of chemistalinoid? Are the self-sufficiency drives one-foreign nations—to discover laboratory-made products to supplant imports or ke out a diminishing native supply—puting to shame the American democratic system of free enterprise.

Such questions have been asked often and as often answered-in the negative Dr. C. M. A. Stine, of the duPont Company, answered them again recently in a talk which emphatically stated that no nation anywhere, whatever its form of government, has surpassed this coun try either in the quantity or quality of the new materials of its industrial science 'American chemical products now represent half the world's output We have established our self-sufficiency in dyes and most drugs, we make nitrates from the air and camphor from southern turpentine; and silk, bristles, and gut may some day cease to be imported products for we have a new synthetic, nylon, which can take the place of all three and can as well be made in sheets and solids. Several rubber substitutes are available to give vital aid in an emergency, and if we were faced with a shortage of wool, we could make a substitute from milk from a formula already known Indeed, scanning the chemical field we find that practically everything announced-with the layman correspondent's usual awe-from Europe is already an accomplished fact in America but simply not commercialized because we are not economically hard up, or else is in the laboratory ready to emerge when needed.

Dr. Stine's statement that "more than 200,000 compounds wholly new to man have emerged from the chemical laboratory in less than a quarter century, confirms this writer's contention that we have entered upon a synthetic chemical age. Moreover, it bids fair to surpass in spectacular accomplishment, in economic importance, and in social values any other comparable period through which man has passed. Already, gigantic industries have been built on some of the new chemicals-rayon, plastics, and now comes nylon-while a host of smaller ones have grown up around hundreds of lesser chemical developments. Other industries will certainly spring from the new prod-ucts now being worked out painstakingly by thousands of our most brilliant chemists. Their success is assured because their approach is right; they have ceased looking upon wood, eval, mutal, filters, and the like as raw materials and have agone further backward to have elements. They now wook primarily with carbon, oxygen, hydrogen, and nitrogen—from the uir, water, soil, from coal and many forms of plant life. The superalundance of these elements promises, in our opinion, long life to the new Synthetic Chemsal Age $\sim P_c D_c M$

Safety for Private Fliers

TraceEDY stalked two young available to recently—and caught up with them in a log over long Island. New York And the truly unfortunate part of the whole affair was that their deaths could have been avoided with facilities that are available but were not in use at the time. If it were compulsory that private planes he equipped for two-way radio communication, it is quite likely that these two young men would still be alive.

The way it all happened was this: Having rind a plane for a weekend trip, the flors started from a point in Connecticut and headed for Long Island. The weather was good at the point of take off and flying was uneventful until fog was encountered over Long Island Carding lower and lower in an effort to get their bearings or make a landing, a wing-tip struck a water tower and the plane dashed to the goound.

While it is true that weather reports could have been obtained it these men had landed at one of the large airports. Connecticut, such information was not available at their starting point. Without radio equipment they could not obtain reports en route, and thereby his the point of our plea. Simple, lightweight, relatively inexpensive two-war radio equipment is available for aircraft use It enables the plot at all times to keep in touch with ground stations, to know in advance what weather conditions are ahead of him and thus to be prepared for any emergency. Knowing, for example, that there is fog at the anport toward which he is heading, he can

turn back or land safely at a nearby field. There is nothing new or untried about aircraft radio. It is in daily use by antransport lines. It has proved its value times without number. But there is no rule or regulation that makes its use on rule or regulation that makes its use on the Civil Aeronautics. Authority should take over immediately. With two-way radio equipment on private planes, especially those for hire, their pilots would have the same safety advantages as do those men whose daily routine on

the art transport lines has piled up such that an envaluble record of flights completed without accident. The radio weather resolvent postering system is in operation. The proving state is a simple system of the system in the case of the constraint of the case in the case is not set of the does for his own safety and for the good of aviation as a whole -A, B, P is the case is some constant of the system of the case of t

No Peace On Earth

RARLY in 1929, just a decade after the world's preoccupation with its War Number One had relaxed sufficient ly to permit it to become for the first time aware of Professor Einstein and his theories, transatlantic cables announced that he had completed a new theory bringing under a single set of laws the phenomena of electricity and gravitation In the intervening ten years the preshad so surrounded him with an atmosphere of mystery and romance that people flocked to his Berlin apartment and Fran Einstein told reporters that he was being driven crazy by the attendant publicity He acquired a worried and nervous manner and a defensive exterior and pleaded that he hated publicity,

The absurd antice of an absurd would struck hum a rulevoluse. So inflated vascurossty in this nation that one enterprising New York, newspaper went to the expense of cabling his published paper from Berlin—which would not have been an unusual feat had his written hury not consisted almost entirely of the must abstruce mathematical hierarchy of the paper from the properties of the propert

In the meantime the great physicist hid behind the iron door of his attic retreat, with his piano and fiddle and small telescope, until the persecution waned.

A few vears later another variety of persecution diver Professo Enstein to this country, where he thought persecution duals read, yet he never has been quite able to escape it. While the dozen reporters who are themselves scientifical by backgrounded have behaved admirationally of the professor of the persecution of the professor of the profess

Now he has announced another try at the field theory and in doing so he has actually been forced to leave his home and hide from the hounds of undesired publicity. Our national nosiness drove Col. Lindbergh from his native land: Are we now to drive the great physicist away again or else crazy?—A. C. I.

50 Years Ago in . . .

(Condensed From Issues of May, 1889)

CANAI—"The most serious feature of the Nicaiagua canal project, in a contracting and financial sense, is the great rock cut at the eastern divide, 3 miles long and averaging 120 feet deep by 80 ft wide on the hottom, containing in all some 7,000,000 cubic yds. of material, or say 440 cubic vds. per lineal foot."

WATER—"One of the grandest engineering works of modern times, undertaken by the Corporation of Laverpool to supply that extra undertaken by the Corporation of Laverpool to supply that extra vialety bully up among the monotants of North Wales, is no nontants of North Wales, is not providing its successful consummation. The stone of which there were the constraints of the constraints of the successful consummation and the stant.

PRINTING. "Inglish and Stotch manufacturers of machinery are beganning to find out that transverbastanding their proverbal preparation to many things, wherevan there catalogues can best be this tracted on this soft of the Atlantic, and many firms are now not only getting the capacing does in this country, but also the printing.

BOSTON ="The Boston Herald says that one-third of Boston is now resting on spince stills, some 112 ft long, though in ordinary cases a length of 30 feet is sufficient But in certain localities "much boles" occur which require piles of over 100 feet in length to reach firm bottom."

BURLS—"Burls, used in making concers with remarkable exertractive of grain, are exerciseness that grow upon various trees, such as the walnut, inservood, malogany, oak, and ash. They weight from 1000 to 6000 pounds, and the largest and hest come from Percas and Cruss-sia, and cost in the rough from 15 to 40 cents a pound."

RABHTS—"It is stated that M. Pacieur's plan of exteriminating rabbits by inoculation with transmitable virus has proved to be a failure in Australia. The reward of 100 000 dollars offered by the N.S.W. government for an effective mode of distroying the rodents is as vet unclaimed."

TELEPHONES—"The Medical Press says there is talk of applying telephones to the infectious wards of the French hospitals so as to enable the six people robusted in their configuous sufferings to have the confort of hearing thoir relatives voices without any risk of consystem infection by an interaction."

MILK—"It is said fresh milk may be preserved indefinitely by freezing it and maintaining it in the freezin state until wanted for use Many of the stramers now sailing on distant voyages are provided with steam refrigerators, in which milk and other foods may readily be preserved for any leight of time."

EEFIL—"there are three systems of elevators to be used in the Fifel tower From the ground to what may be called the first store, where great restaurants will be established, there will be four elesators, two of the Otte pattern and two of the system of Rima, Gimbaliurer, and I epape. From this story to the next or, along 400 detect from the ground, the Otts cleavors only are employed, in two of the legs of the tower. The top lift, a vertical distance of 493 levt, is made by cleasures on the Faboux spelar, in which the carrage is worked by an enominous poton. Those who go above this distance to the latents will have to takin a speral sturring."

morth. The stone was too hard for pick work, hammer and closel or hammer and st, were, therefore, almost exclusively used. When brought to the dam by loromotives and wagons running on a 3 for gauge railway, they were lifted into position by seam cranes and deposited on a bed of Portland coment mustar. The total length of this buge masonive dam across the mouth of the valley is \$1172 feet, its greats thinkness at the base is \$2.0 feet, it is right with which was the first highly from the lowest part of the foundation to the parapet of the carriage road on the top, is \$10 feet."

STEAMER." The first trip of the new passenger stramer Particles of the Fall River line, from New York to Novport, via Long Tenland, and of the Fall River line, from New York to Novport, via Long Tenland, and Sound, was made April 21, with much success. She attained a speed of over 20 miles an hour with 61 pounds of steam. When het no the third with the first shear of the pounds of steam, when het no the third with the steam of the first shear of the steam of the steamer line is believed by will surpass, in well not pure passenger loan afind."

WAR SHIPS—'According to a careful estimate, the number of war tessets haimhed last year by the naval powers of the would was 60, while more than 100 were hubbling when it closed England lof, with 15 vessels kaunched and 22 hindling. France Launched 9 and land down 15. Russa hannched 2, and began 10. Germany put 6 vessels mot be water, and ordered or land down a 1, lady launched 10, and land down 18 — Japan ordered 3, and launched 3, the United States ka neithed 6 and land down 6"

IRRIA/TION—The Russan government devided about a year ago to commence some irrigation works near Mercy to the purpose of rendering the crown lands more suitable for the cultivation of coltion, and during the period which has since clapsed the first part of the scheme has been completed. A dam-30 feet high—has been built across the twee Wignels, in the Merc west, at a distance of fifty miles from the village of Sultanburd, and the wast quantities of water which are collected in this manner are lowing distributed to the

Personalities in Science

In recognition of outstanding achievement in physical chemistry, Profesor Joel Henry Hidderand, of the Unversity of California, has received the William H. Nichols Gold Medal of the New York Section of the American Chemical Society, Professor Hildebrand is the thirty-third chemist to receive the Nichols Medal, founded in 1902 "to stimulate original research in chemistry by the late Dr. William H. Nichols, chair to member of the American Chemical Society, and leader of the chemical industry in this country.

More than 400 scientists united in honoring Professor Hild brand, who was cited for "his study of the solubility of non electrolytes." The scientific accomplishments of the medialst embrace morthan 30 years of research on liquid and solul solutions.

Triof-ssor Hildebrand is internationally known in the broad field of plys at all chinistry. More than that, he has been one of our few contemporary real teachers of chemistry. His public service has been of the highest order. His work in chemical warfare has contributed greatly to our national defence, both in the held and in the laboratory. His whole life has been one of service to science and the public weal.

In responding with his medal addresson "Order and Disorder in Pure Liquidsand Solutions," Professor Hildebranddeclared that "the shapes of moleculeshave important effects upon the properties of pure liquids and the solubility of one in another.

"The molecules of mercury, for example," he explained, "are spherical, those of parafin are shaped somewhat his ausages, those of benzene are flat hexagons, while water molecules are right-angled.

"Liquids and concentrated solutionhave been much harder to deal with than gases or solids. Some of the earlier theories pictured liquids as analogous to gases, others as quasi-solids. Recently, however, the efforts of a number of competent investigators are combining to develop a general theory of the liquid state more in accord with the actual properties of liquids and solutions.

"Light recently thrown on the structure of liquids has been largely responsible for this progress. The scattering of X rays has been a most powerful means of revealing structure, not only of solids, where a large body of knowledge has al-

IOEL H. HILDEBRAND

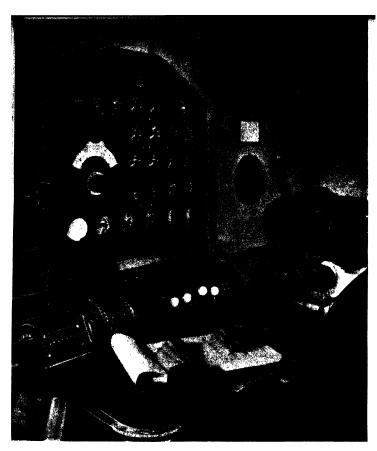

ready hern accumulated, but also of liquids. In the case of solids, a lattice structure is revealed, but with liquids the structure is best expressed by a so-called 'distribution function,' a wavelike curve which expresses the frequency at which molecules are found at different distances from any one molecule arbitrarily chosen as a center of reference.

"An artificial model has been con structed, which corresponds closely with the structure of mercury as revealed by X rays. The model consists of gelatin balls suspended in a solution of gelatin, which has been boiled to destroy itpower to set."

During the World War, Professor Hildebrand was first commissioned captain of the Ordnance Reserve Corps, then major and later licutenant-colonel in the Chemical Warfare Service. A director of the Chemical Warfare Service laboratory at Puteaux, near Paris, and as commanding officer of Hanlon Field, near Charmont, he played an important role in organizing the American Expeditionary Force Gas Defense School and the experimental field for gas warfare research under practical conditions, for which he received the Distinguished Service Model

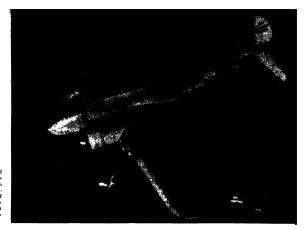

He suggested to the United States Buround of Mines the use of a mixture of helium and oxygen in place of air for divers and caisson workers to interduce the dangerous carseum disease or "bends." The effectiveness of this artificial atmosphere was recently demonstrated by Max Nohl, engineer, with the collaboration of Dr. Edgar End, physiologist of Marquette University, in increasing the reord for deep driving by 100 feet.

Professor Hildebrand is a member of the National Academy of Sciences, a past president of the American Physical Society, and a fellow of the American Association for the Advancement of Science. He is president of the Sierra Club and in 1936 managed the United States Olympic Ski Team

NERVE CENTER
OF THE "YANKEE CLIPPER"

IARCEST aircraft in the world, the Yunkre Chpper, Lidesigned for transoceanic passenger service, is the first of a fleet of six being built by Boeing. The ship is an all-metal, double-deck flying-boat powered by lour 1500-horsepower Cyclone engines. She were discommodate '74 day passengers or 40 passengers in berths. All engines are accessible for servicing or repair during flight. In the photograph is shown the Engineering Officer at his post where are grouped the instruments and controls for the power-plants. From this point he can communicate by telephone with any of the Flight Officers at their respective stations.

The flying laboratory of United Air Lines Here is carried on research work that, conducted under actual conditions of flight, yields results which will directly affect future airline policies

How Safe Is Air Travel?

THE question, "How Safe is Flying?" is in the minds of 90 percent of the people today who do not travel by air, fear of flying is the reason given by all but 10 percent of non fliers when they are asked why they do not travel by air,

This fear is wholly out of proportion to the actual risk involved in modern an transportation.

It is predicated on ignorance of the tapid advancement in air-transport operations. It is exaggerated by imaginary conceptions of the inherent and natural obstacles to flying in the form of air pockets. tail spins, and other bugaboos It is aggravated by dramatization of airplane accidents---airline, private flying, military, and otherwise- which over-emphasizes the extent of airline accidents. It is being gradually eliminated by educating the public and familiarizing them with the facts of the case. Complete public acceptance of air travel will come sooner. perhaps, than is expected, because of the speeding up of visualization facilities for the exchange of thoughts and ideas, and because aircraft manufacturers and accessory producers are going persistently about the job of taking every "if" out of

In 1938, the airline accidents claimed 25 passenger lives in air-transport planes in regular scheduled operation and flew 22,445,019 miles per fatality, a mileageper-fatality increase of 88 percent over Rapid Advance in Air-Transport Operations Has Been Made Possible by Applied Research That Aims To Take Every "If" Out of Air Travel

By R. E. JOHNSON

1937 when 40 passengers were killed during a year that scheduled planes flew 11,915,079 passenger-miles per fatality Six times as many people were murdered in Chicago during 1938 as were killed in all of the domestic air-transport accidentiouring the same year.

The artimes' record is one that stands up well under close seruiny and attestthe success of engineering concentration on those factors which in the past have contributed to aitluse troubles. In barely more than ten years air transport last year celebrated its tenth anniversary of air passenger service in the United States— — the airlines have inexorably climinated obstacle after obstacle in the pathway of the highest possible rate of operating de-pendability.

M ECHANICAL failure was a frequent factor in flying ten years ago. This covered a multitude of troubles, the principal one of which can be considered as engine failure. In the early days of single-engined operation, engine failure was a fairly common occurrence and it meant at least a forced landing on the spot. Another cause of early day accidents was getting lost, which paved the way for such accident-causing situations as getting off the airway and getting into terrain considerably higher than that on the route, running out of fuel, and so on.

The problem of radio static, which may cause the pilot to get lost by interfering with his use of radio navigating and communication facilities, has figured prominently in certain accidents. We after likewise has long been a trouble-maker for air lines—ice, fog, unexpected high-veloc

aty winds at upper elevations and so on. These, then, have been the principal causes of acculents, engine and other mechanical failures, failure of the hu nan element, and weather But many things have been done about these conditions in the last few years both in the development of facilities specifically intended to eliminate accident causes and in policies and practices designed to neutralize the human element as the unportant factor which it has been in the past. Consider mechanical failure, for

A laboratory set-up for creating man-made static for use in testing aircraft radio equipment

example Modern aircraft engines are truly standards of precision and mechanical efficiency Instead of engine failure being frequent, or even occasional, it is very infrequently experienced in modern airline operation Furthermore, there are two engines on modern transport planes, each capable not only of sustaining flight, but also of enabling the airplane to climb as high as two miles above sea level. Thus, in the event of the failure of one engine, the modern an liner. unlike the plane of 1928, can continue with adequate power produced by the other engine. In every other respect there has been mechanical refinement and application of precision workmanship to the point where the modern airplane is an extraordinarily efficient piece of equipment constantly maintained in that condition by the operating machine.

Title questions of weather and human lebenation of very less that the recognition of weather conditions and the use of judgment in dealing with those conditions rather than the presence of the conditions benedless, that determine the effect of weather on airther operation For example; Today's airplanes are equipped with efficient design equipment in the form of boots along the leading edges of wing and tail design protection for the propellers flowerer, under extremely severe ising conditions, airplanes with this protection constill get into trouble

Modern arthres diagnose weather conditions to determine the presence and degree of seing conditions. If they are severe, flights are dispatched around the conditions when that is possible, otherwise they are cancelled Science will executually bring to the ariplan complete protection against any and all leng conditions but, in the meantine, arthese are exercising conservative discretion in the use of the facilities now available. This is the underlying principle of all transport policies and practices and to a great expolicies and practices and to a great extent explains the high safety record attained by domestic artines last year. The recognition of the margins which are allowable on various equipment under various conditions, and the constant adherence to the conservatives do of those margins, spell the success that is now attending the advancement of United States arrine operations.

Under certam weather conditions, static interference is so had as completely to put out of commission all radio contact with the ground, either by voice or by directive addo-range signals. Years ago, United Air Lines established

a project to attack this problem of static and uncovered information that paved the way for a solution that is as simple as it is effective. After extensive research and experimentation in laboratories, both on the ground and in the air, a simple trailing wire device for the cradication of static was developed and installed at the close of 1938 on all United planes and made available for installation on other airlines. By pressing a button which releases the wire from the tail of the airplane the pilot can eliminate the noises that range from sounds simulating bacon fixing over a hot fire to the crashing of cymbals

The importance of this development to the safety of air transportation may be better appreciated by realizing that certain accident have been caused directly and indirectly by lack of such protection against static. Now this simple length of wire, with one end attached to the metal tail of the airliner and the other to a paper drinking cup, which parachites the wire out into the slip paream and holds it extended, sends this

once paralyzing static streaming off harmlessly into space, keeping always clear the precious code radio-range signals and two-way voice messages between the plane and ground stations.

Check and double check and even triple check is the by-word of airline engineers in their offensive against acci dents. Trouble was caused in the past when an airplane, flying in the clouds on instruments and losing its radio reception because of static, drifted off its course and flew into terrain substantially higher than that on the airway itself. Several problems of facilities and policies were involved in cases of that kind. One of them, of course, was the elimination of static, which has been accomplished. Another was the development of a device which would tell the pilot how high he was above the ground and warn lum should be approach terrain as high as his flight altitude

THE outhodox allumeters, of course, freezed elevation in terms of sea level. When a pilot is on course and knows his position, he can easily calculate his classification above the ground by compensating his elevation above sea level with the hess allutude of the terrain over which he is flying. But if he is not sure of his exact location he cannot determine exactly the height of his flight level above the ground.

For more than two years United worked with Western Electric and the Bell Laboratories to develop the answer to to this problem. Recently, in a series of or exhaustive tests and demonstrations, the calculations answer was made public in the form of a terrain clearance indicator, or an obstruction indicator, which in reality is a radio altimeter recording the plane's ele-structure of feet above the terrain.

Still another way to solve the problem is to establish prescribed flight altitudes below which pilots are not allowed to

Checking depth perception of an airline pilot's eyes

fly. These altitudes, varying on divisionaccording to height of the terrain along the routes, are for instrument flying-a least a half a mile above terrain at all times-and are adequate to clear the highest points for some distance on either side of the route As a check on the maintenance of these altitudes, the airline maintains an automatic recording barograph in the tail of each airplane This device constantly charts the elevation of the plane's flight and is checked by the dispatcher at the end of each flight to make sure that minimum altitudes are being maintained, Penalties for deviation from these minimum altitudes, without express permission under conditions which would make for increased safety are as severe as possible.

COMMERCIAL application of instrument landings is practically in effect, with the completion of installation of landing system apparatus at eight auports in the United States and the plans of airlines soon to install necessary recoving equipment in transport planes.

In August, 1937, a series of instrument landing demonstrations were made at Oakland Municipal Airport before commercial airlines, Government civil air authorities, and military aviation officials. These demonstrations culminated five years of intensive work and pavol they were soft intensive work and pavol

Equipment in the nose compartment of the airplane shown on page 279

the way for the successful completion of the instrument-landing method.

A basic instrument-landing system had been installed in Oakland by the Department of Commerce in 1933 and turned over to United for any use it might make of the existing equipment. Pilot R. T. Freng, now director of flying for the company, did the major share of the actual flying during the experimental program and, in 1934-1935, with the cooperation of J. R. Cunningham, Director of Communications, developed the use

of the automatic pilot in instrument landings. Their work simplified the problem and paved the way for a ready acceptance of this important aid to all safety. Freig made approximately 475 landings on the instrument landing system during the development period

Because judgment is so important in air transportation, the airlines have been developing their personnel to increase the effectiveness of the judgment exercised. For example, one an line, through its own school of aeronautics, provides a thorough and complete system of home study training to all employes at no cost Its employes thus are educated in the latest safety aids and practices. Practical courses covering every phase of airline operation-meteorology, power plants, mechanics, navigation, air lawhave been developed by the faculty of the school and department heads of the airline.

These courses are made available to all employs, who may take any or all of those included in the curriculum Certain courses are required. For example, all fixing pr isomic have been studying increorology and advanced meteorology in the past three years. In many cases the courses are conducted in seminars, and, in any case, the student's work is thoroughly checked and a written report on each lesson is given by the furthy.

The purpose of the extensive homestudy program is both to improve the employe's ability and efficiency in his particular work and to develop him and prepare him for advancement. The net effect is considerably increased efficiency in employee.

Sulf another move he mg made by the airlines on the scientifically laid out program of accident elimination is in the media al direction. Every airline mains health cliently gestero for it flight personnel, but Colonel A. D. Tuttle, MD, formerly Commandain of the Aimy's School of Aviation Medicine and now company medical director for an airline, has gone further and has just completed the world's first continuing medical study of the physiological effect of flung on passengers.

Representing an examination of the records of 261,370 passengers carried on one airline's planes during the past year, the study showed that only 0.59 percent of passengers's suffered discomfort of any kind, including nervousness," Colonel Tutle stated

Only three passengers in a thousand were troubled with air sickness, a rate not only much lower than that applying to sea-sickness, but one comparing favorably with land surface transportation, according to comparisons made by Colonel Tuttle with National Safety Council statistics.

Aside from air-sickness, one interesting feature of the study was the fact that there were cases of ear trouble reported in only 0.05 percent of all passengers earried during the entire period. Despite the notice occasional evidence of the effect of altitude changes on the cars of passengers and during ascents and descents, the survey revealed that only 1441 out of 261,370 passengers underwent ear discomfort. This can be attributed to the company policy of restricting descents to a rate not to to exceed 300 feet per minute to the notice of the pressure is

Hearing of an pilots is regularly tested by means of an audiometer

not too great for compensation in the ear

Although numerous estimates have been made in the past as to the prevalence of air-sickness, ear trouble, and other discomforts, this is the first authoritative study to be made on the subject to determine the real facts in the hight of modern air transportation.

ingo or modern air tensportation. It is believed that, if the continuing study had been started several years ago, results would have been definitely less favorable in respect to the observable to the observable to the observable area of air scheenes, in fact, it is quite probable, according to Colonel Tuttle, that five years ago, or even less, the percentage of those passengers discomilited by air sedkness was substantially higher than is now indicated and very probably approximated the estimate of 3 or 4 per cent made by airthe publicity people.

In those days airplanes flew at relatively low levels. Flight altitudes of 1000. to 2000 feet above the terrain were average and in the case of schedules operating in the face of appreciable headwinds. even lower cruising elevations were maintained. This alone aggravated susceptibility to air sickness as those flight conditions much too frequently encountered rough air. In contrast, today's operations average from 4000 to 6000 feet, and even more, above the ground; generally speaking, at those flight altitudes smooth air is the rule rather than the exception. Almost invariably the air is smoother at high altitudes than at low altitudes.

Animals Bring Us Diseases

ANIMALS are carriers of certain discusses which can be transmitted to man despite the mological gast between him and the animals in his modiate environment Several such discusses entered the news recently. Typical for example, broke out in Poland among Jewish exiles from Germany, Tularema, or rabbit fever, cass schowed a sharp increase in the United States in 1938, Rocky Mountain spotted fever, having journeyed across the nation to the east, enterenched utself more fermly in the

Pets, Domesticated and Wild Animals Carry Bacilli Deadly for Humans . . . Are Hosts to Parasites Causing Serious Human Ailments, Death

By WHILLIAM WOLF

Animals provide food for man, they serve as heasts of burden, they furnish fur and wool for clothing. Man lives intimately with some as pets and he toler-

ates the existence of rodents. The pine paid for this proximity and employment of animals sometimes is illness and death. It is a needless payment, too; for, with a few exceptions, every one of these diseases could be controlled or eradicated.

Trichinosis, the most important of these diseases at present, is caused by a small nematode worm, the Trichinella spiralis, which is found in the flesh of swine, and some other animals

Man takes in the trelining through eating pick products, and in the human holy they enter the digestive tract, the hymphatic, systeme, and pulmonary in entations, the brain, the heart musclesand the strated, skeletal, and other muscles as criculating larvay, matured adults, or as degenerate larvay which become encysted—and eventually calcified— —in muscular tissue.

Here is a brolth menace of major proportions, for there is no reason to doubt Public Health Service investigators' conclusions that 12.5 percent of the court try's population is affected, Indeed, that percentage may be daugnoved as almost anything, some 50 disease conditionhaving been listed as having been confused with trichinosis. The number of trickinae in human beings depends entirely upon the number ingested, for they do not multiply in the body of man.

PIGS become carriers of trichinge in various ways, but the most important is through the consumption of garbage containing scraps of raw or partly cooked pork infested with trichinae This accounts for the fact that the high est averages of trichinosis are reported from Boston (27.6 percent of the population) and San Francisco (24 percent), since both the eastern and western seaboards have large garbage-feeding establishments supplying pork. In acorns, grain, and vegetable feed with the result that the southern states have the least number of cases. Where hogs are grain-fed in the midwest, there is little trichinosis.

In recent studies on trichinosis, Maurice C, Hall and Benjamin Collins, of the U.S. Public Health Service, emphasized the fact that Service, emphasized the fact that pork is a wholesome, desirable meat, and that the widespread prevalence of trichinosis is not a reason for not eating pork.

a reason for not eating pork. but an excellent reason for cooking it well. Thirty minutes to the pound for large, thick cuts is an approximate cooking guide.

Making a culture of anthrax in the laboratory using infected goat hide with other pieces of hide in the search for a disinfectant Below: A clipping from a New York newspaper

Moddle Atlante states and caused a number of fatalities. More alarming was an epidemic of hubonic plague among rodents in the far west, for this dieaded pestilence of the past is carried to man by bries from fleas which desert infected rats and squirriels.

These, plus endemic outbreaks of tables, held the public's interest; but other diseases carried by animals and acquired by man are far more common and cause greater health and economic concern It is estimated, for example that 16,000,000 persons in this country are infected with trichinosis alone. This means that one out of every eight is a victim of this disease caused by a parasite found in pork-a staggering average which gives the United States the highest incidence among all nations. Bovine tuberculosis and undulant fever are among the other important animal conveyed diseases, while the lesser ones pose their own health problems.

Unlike trichinosis, bovine tuberculosis, another disease contracted from animals, has been studied and well under control for many years.

The consumption of raw milk from infected cows spreads this disease to human beings. However, county by county, year by area, and state by state, tubercular cattle have been eliminated from berds until today the percentage of reactors to the tuberculin test, devised by Robert Koch in 1890 and later improved, is only 0.7 percent, whereas in 1917 it was 3.2.

Choosie brucellosis, or undulant fevr, another human disease due to the use of raw, or unpasteurized, milk, is increasing, however. By the end of August, 1938, there were 2000 reported cases in this country, twice as many as in all of 1937, indicating a peak year. The first reported epidenuc here occurred at Phoenix, Arivona, in 1922.

Medical interest in undulant fewer dates back to the Crimean War when thousands of British soldiers in the Mediterranean basin were stricken with Malita fever, a variant caused by goal's milk in 1886, the germ was discovered; in 1897, the germ causing contagious abortion in cattle was isolated, and in 1918, bacteriologist Alree C. Exans, of the U.S. Public Health Service, announced that the two were closely related, later proving that the human disease ongunates in cattle, goats, and swe ngnates in cattle, goats, and swe ng-

The disease often is mourretly diagnosed because its middle form resemble influenza and the more severe attacks are imiliar to tuberculosis, rheumatism, typhoid, and malaria. It receives its name of undulant fever from the distinguishing tidal fever which advances in the afternom, reaches a peak from two to fee F.M., and then recedes in the evening. Fatalities fortunately are rate, but the disease leaves the heart weakened

TWO tapeworns better illustrate the close and long-continued relationship between man and domestic food animals than any of the preceding discases, for their immature or larval stages are lived in animals and their adult stage only in man. Human beings, in other words, are essential to their life vycle. They are the pork tapeworm. Taenias solium, and the beef tapeworm. Taenias solium, and the beef tapeworm. Taenias solium, and the beef tapeworm the small intestine of man when released by the digestion of raw or slightly-cooked meat.

In 1934, some 300 inhabitants of Sackville, a woolen-working fown near Philadelphia, packed up and deserted their homes in a dramatic mass exodus because the 134-year-old village was threatened with a major outbreak of anthrax. Anthrax is an infectious disease attacking the skin, respiratory, or digetive systems. It is caused by a specific micro-organism, the anthrax hacillus,

The first line of defense against the importation into this country of bubonic plague and typhus fever: ship-fumigating squad at a U.S. Quarantine Station

and is common to cattle, horses, sheep, goats, and wild herbivorous animals.

The exhidreal bacilli, on being released from an animal's body, produce, on contact with air, elliptical spores highly resistant to heat, cold, drying, and disinfectants. In the Sackwille case, the antinax spores were in the soil and in the old houses, and the bacilli and spores were in the factories where the men worked.

Man acquires the disease through handling woot-hence the name "wool-carders' disease"—from hides in leather-working establishments, from infected careassis, or from the soil. Pennsylvania, a tannery center, gets from 15 to 20 anthrax cases annually. A fourth of these himan victum soil.

Glanders can be contracted by man from horses and mules, but is of little importance medically Horses, however, are responsible for an entirely new faccuse, encephalomyelits, a brain infection which killed a dozen children in New England executly. It is carried from horses to human victims by the bites of mosquitees.

The cry of 'mad dog' still rouses terror in human being, for ratios is a 100 percent fatal disease if contracted, although the Pasteur treatment, in general use for several decades, is 100 percent effective if employed in time. This nation, strangely enough, tolerates rabies, According to John R. Mobler, of the Bureau of Animal Industry, 'there is no communicable disease which is more easily prevented and eradicated than rabies."

Rabies is conveyed to man, of course, principally through the bites of infected dogs or through saliva from a rabid dog entering a break in the skin. Five years ago a three-months-old puppy became a pet in a California C.C.C. camp and developed rabies, Seventy-two persons, including 62 C.C.C. men, four U.S. rangers, and six civilians were bitten, licked, or otherwise exposed, and all 72 took the Pasteur prophylaxis.

There are two types of rabies in dogs: the furious, violent, or irritable, and the dumb, or paralytic, type. Furious rabies are of greater concern to human beings, for the violent dog will roam, fight, and late. Cattle bitten by rabid dogs develop both types. Cats usually contract paralytic tables.

The Pasteur treatment has no curatic value and is useless after rables develops, which, mercifully, isn't until approximately a month after exposure, allowing time for the treatments, Usually 14 injections are given, but in face or neck wounds a series of 21 or even 28 will be administered, Bites about the head are particularly dangerous because of their proximity to the brain and spinal coid.

NOT all bites from tabid animals cause rabies in man. The tirms extransmitted in about 30 percent of cases; but all persons exposed should be given the prophylazas. There are occasional curious cases of lysophobia, or peudo-tables, in which the imagination creates all the symptoms of hydrophometers all the symptoms of hydrophometers.

The cost of rabies to this country is not reckoned so much in the number of deaths—about 100 a year—as in suffering and anxiety. And it is so easily climmated. Denmark, Sweden, and Norday have practically eliminated by the away have practically eliminated it by requiring that all dogs at large should be muziled. Great Britain was free of rabies for 16 years until 1918 through strict quararnines; then the disease en-

Photographs Gantes Atmy Medical Museum Lungs and windpipe of a rabbit killed by tularemta. Diseased parts are grayish spots with darker centers. At right: Primary ulcer from handling tularemia-infected rabbit

tered the country again and was not checked until 1922. Since then there have been no further cases.

Man's pets are responsible for other human diseases, and the dog is guilty a second time in the case of the eastern type of Rocky Mountain spotted fever, for canine carriers spread the American dog tick which is the vector of this disease. An average of 140 cases are re-ported annually in the eastern and southern states, an incidence which seems to be increasing. The human mortality rate is about 25 percent-high enough to put spotted fever in the deadly disease class The western Rocky Mountain spotted fever, caused by the wood tick, Dermacentor andersons, which is common to many rodents, is even more virulent, 75 percent of the cases in central western Montana concluding fatally. The American dog tick, Dermacentor variabilis, spreads westward along northern boundary states, overlapping the domain of anderson.

Both ticks are blood-suckers, feeding on human beings at the harry back of the head or the armpits and, if infected, spread the disease to their human hosts,

spread the disease to their human hosts. The same ticks may carry tularemia, tick paralysis, and Colorado tick fever, a mild infection without the skin eruptions which characterize Rocky Mountain spotted fever.

Pottacosis, or partial fever, deserves some mention under the discase canned by pets. It is borne by the politacine birds such as partots, parrackets, Amazons, Mexican doubleheads, cockatons, macaws, and lowbirds and is caused by a mysterious virus about which the preent knowledge consists largely of the fact that it is filterable, as demonstrated in 1930. A major outbreak occurred in 1929-30; another in 1932 caused restrictions to be placed upon the importation of carrier birds. In adults over 30, the disease was 24 percent fatal.

The world-shaking great plagues of the past are not dead—only sleeping. The "Black Death" which swept Europe in the 14th Century, destroying one fourth of its population; or the "Great Plague" of London which killed 70,000 in 1665, are no farther removed from us than the states of California, Nexada, Montana, Idaho, Oregon, Washington,

and Utah, Not that many human beings are affected in those states, but rats and squarrels are victims and the disease is pread to man by fleas which desert plague-killed rodent hosts. There were five human cases early in 1938, enough to make the U.S. Public Health Service increase its efforts toward externinaing rats and ground squirrels in the area. Health officials were not caught unprepared, for they had warning in 1924 when the plague struck 24 persons in Los Angeles.

There are two types, the bubonic plague, transmitted by fleas, and the deadly pneumonic plague which can be carried by the bites of infected animals or even by the breath of stricken humans. In the latter, there is a high fever, constant coughing, and usually fatal termination in three or four days.

Typhus, a highly contagious fever, is another plague borne by fleas and lice from rats. At present it is an ever-present menace to world health, for a typhus outbreak followed the cholera epidemic in China's war zones in 1938; and, in Spain, refugee camps swarming with women, children, and vermin create ideal conditions for an epidemic that could easily become pandemic. The means of prevention are at hand here, however. In 1932, Dr. Dolla E. Dver. I.S. Public Health Service, developed a vaccine for the flea-borne type and then Dr. Hans Zinsser, of Harvard, prepared a vaccine for louse-borne typhus.

Some idea of what typhus means to the human race can be gained from past epidemics. In 1914, the disease killed 150,000 Serbians and 30,000 of their Austrian prisoners of war. From Serbia, it spread to Russan where it attacked the amazing total of 25,000,000 persons, killing 3,000,000. It was kept out of the United States by de-lousing American skildiers before demobilization.

soldiers before demonstration.

Rats also are responsible for occasional cases of rat-bite fever and infectious jaundice. Man acquires the latte through eating, touching, or drinking food contaminated by contact with infected rats.

TMLAREMIA, or tablot fever, is the last of the important rodent-carried diseases and has caused recent consternation among health officials because of a sharp increase in cases, Illinois waparticularly hard hit last fall with 10 deaths in less than a month and 243 stricken, but other widely-scattered states had fatalities. The Moddle Atlantic states reported a number of deaths East SI tons, Illinois, barred the sale and transportation of rabbits after 26 cases within 15 days.

The disease is acquired by handling the flesh or entrails of infected animals with the bare hands, or through the bites of various tularemia infected insects, in cluding the Rocky Mountain spotted fever tick. An ulccr usually marks the site of infection, appearing two to eleven days after infection. If the infection is from an insect bite, the ulcer usually appears on the neck, face, hands, or arms or other exposed areas: if from a tick, any part of the body but the feet. if from contamination through handling infected animals, on the hands. Chills and fever, profuse sweating, and painin all muscles follow.

The active organism is Bacterium tuharcus: the name of the divesee being derived from Tulare County, California, where the first outbreak among grounds squirrels was discovered in 1912. Cottontals, jackrabhts, and anowshoe hares cause 90 percent of the human cases, although the divease also is carried by sheep, tree and ground squirrels, sage hens, red fox, ground hogs, muskstats, skunks, cats, dogs, and opossum.

Health officials advise wearing rubber gloves when handling rabbit carcasses, protection against insect bites when in the woods, and extra precautions and prompt treatment if exposed,

Most of these diseases are well under control. The few exceptions fortunately are diseases which can be eradicated by forceful action on the part of public health officials and intelligent co-operation by the general public. Trichinosisfor example, can and will be controlled as soon-as the public awakens. Rabies will be reduced to an unimportant discase as soon as dog owners voluntarily or under compulsion follow the advice of health authorities. Care in the use of raw milk will prevent bovine diseases.

On the Site of Armageddon

RMAGEDDON, ancient city mound A of Megiddo, in Palestine, around which was a frequent battlefield of the ancient nations, apparently was a walled city as early as 3000 B.c. according to Gordon Loud, field director of the Megiddo Expedition of the Oriental Institute of the University of Chicago, The expedition has excavated more than 150 feet of a great stone wall 15 feet high and 21 feet wide, which probably enencled the entire city site. The city mound has been built up from the debris of some 20 periods of civilization. The expedition made a large cut through one section of the mound only, but the wall continues into the unexcavated portion

Characteristic of early Bronze period construction, the wall shows considerable skill in the workmanship of the points of the rough timestone blocks. The two faces of the wall are much more carefully constructed than the more part, which was filled with stone and rubble Apparently the original thickness of 12 feet was inadequate, for the construction shows that the width was later doubled.

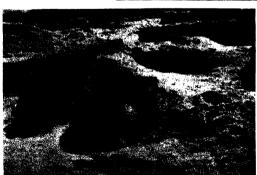

In completing the cut, the expedition reached bed rock—a soft, chalky limestone which slopes away from the site Bed rock is immediately below the 20th level of culture represented in the mound.

The cut exposed one cave in the soft limestone which may have been the home of the first inhabitants of the famous site. Neolithic flints, and sherds and bones were found in the cave.

Part of a large, ornamented flagged paving at stratum 19, about 3000 B c, was disclosed by the cut. Outline drawings of horned animals and of human figures were incised in the stones of the paving.

THE GERMAN NAVY AT A GLANCE

FIGOM pocket hattle-ships instited in size to 10,000 tons up to actual lastfallips of 35,000 tons, Germany has expanded her may effectively in recent years. In this drawing by Oscar Farkes, third of the series which we publish through the courtew of The Illustrated Landon News, are shown typical ships of the new German navy. It will be remembered that by the Anglo-German agreement, Germany's tonnage in no

category except submarines may exceed 35 percent of British tonnage. This restriction is not, however, as stringent as the bare figures would indicate. Creater use of welding and of lighter metals assisted Germany to devote a larger proportion of tonnage to protective armor and to crowd greater for power on a given hull. This practice, first observed in the "pocket hattleships," will thake the new 35,000-6m battleships.

ships higger and presumably superior to sumlar new ships mother navies. While the drawing (made some time ago) in-dicates two or three such 35,000-somers, recent reports have it that three are now under construction and a fourth one is authorized. The first of thees, the Bisman et, was launched last February. These chips will mount eight 15-inch guns. These guns do not, have the range of 16-inchers, but the Germans seem convinced that firing observation from planes as is necessary with the greater distances involved with the larger

guns, is ineffective. Accuracy of hre would be spotted from the ship herself Furthermore, use of the smaller guns gives an icormous saving in weight, for the 15-inch gun weighs only 844 tons as against 1270 tons for a 16-inch gun. Since the German constructors are still pledged to the pre-war tradition of constructional strength that enabled German ships at Jutland to take a terrific punishment without anking, it may be assumed that this saved weight will be used in providing greater structural strength as well as added armor.

Your Inferiority Complex

EVERYONE starts life with feelings both of inferiority and of superiority.

On the one hand, he can not help having his interiority impressed upon him ring his interiority impressed upon him continually. He is constantly overshadowed hy his hig, strong parents (and other adults) who can do just as they please with him. He can not even get through a door without their help—he is not tall enough to reach the doorknot)—and can only stand and yell until someone comes to assist him.

Things he does with immense effort, or fails to do after endless trials, the grownups do without half trying

How could be help feeling weak and inferior? If he didn't, there would be something the matter with his mind!

On the other hand, the infant is meatiably egocentric, completely selfish, and impressed with his own importance To himself, he is more important than any thing else in the world Lacking perspective, lacking experience of life, lacking ability to judge his own powers, and having a strong will to domainet others (perhaps finding that his parents and others can actually be dommated), of course he develops feelings of supercrit.

During the process of development, these strong but contradactory feelings are gradually modified, tempered, and fused into a normal notulow on the world in which the individual recognizes both his own capacities and his own limitations, profits by both, and reaches a balance which represents entonial maturity, good mental hygene—in a word, sanity

Many, however, never attain this balance. They are overweighted in one direction or the other. They become the victims of complexes.

A complex is merely a group of related ideas strongly colored by emotion Because of this emotional tone, it has the tendency to attract to itself and incorporate in itself all sorts of other and originally unrelated ideas.

One may develop a superiority complex because he is clever, finds that he can do things better than other people with whom he is associated, gets along easily where they struggle desperately—in short, because he is riding on top of the waves. ("It's not conceit," said the Bishop; "it's just the consciousness of superiority!")

Even at its best, however, the superiority complex is largely an infantile type of behavior. The genius does not

Few of Us Attain that Perfect Balance Between the Two Extremes of Actual Inferiority and Self-Importance that Constitutes Emotional Maturity

By PAUL POPENOE, Sc.D.
Director, The Institute of Family Relations, Los Angeles
Lecturer in Biology, University of Southern California

underestimate his own capacities, but he is mature enough, has a broad enough outlook, to know that there are, and have been, other able men in the world, and that none of them has the wisdom to understand fully even the affaits of every-

day life.

Indeed, the greater a man is, the more likely is he to be modest and genuinely humble, as seen almost universally among the great men of science.

The man with a superiority complex is therefore stelly a bright boy who retains the infant's egocentricity, has not grown up though to recognize his own initiations, and will never be, emotionally, anything more than a precondant and somewhat spoiled child. He has the "Little Jack Horner" complex (There is another type of conceit which is merely an over-compensation for an inferiority complex, and will be described later.)

THE interiority complex is probably to commoner, and one hears of it much too often. The idea is by no means new-probably it goes back far beyond Acsop—but in recent years it has become a part of the common vocabulary. A student thinks his failure in college is sufficiently explained by the glib assurance, "But I have an inferiority complex!"

As I pointed out alove, the inferiority complex has a perfectly natural basis in the experience of childhood, and everyone carries through life what might be called a normal inferiority complex, which is largely responsible for his achievements. He works to accomplish something because the recognizes that it has not yet been accomplished, and he is not satisfied with his own lack of knowledge.

If Einstein had felt perfectly satisfied after mastering Newton's ideas of gravity, he would have gone no farther. He would have said to himself, as Buddha did when he stood under the sacred Botree, "I know it all!", and would have been content to spend the rest of his life imparting this knowledge to his students.

It was his discontent, his feeling that he did not understand, which made him continue to work on the subject

In a very real sense, therefore, this normal inferiority complex ("Not as though I had already attained") furnishes the driving power for creative achievement

But the name is usually reserved for an abnormal or pathological state which (due to the tendency of the complex to draw unrelated ideas into itself) leads the individual to depreciate himself, to become unduly sensitive, to be too eager for praise and flattery, to adopt a derogatory attitude toward others.

All this, again, is largely a survival of infantile attitudes which, facing adult difficulties, build up for their possessor a more or less organized system of ideaconcerning his own place in the world

Such an inferiority complex may have grown out of some personal handicap, some physical deformity, or it may be an environmental handicap; or both.

If a girl is quite unattractive, she may easily develop an inferiority complex; but she may likewise do so because her parents are divorced and she feels that she is therefore not like other girls; that she lacks something which they, happy in their home life, have had.

This boy grew up subject to constant tunits and ridicule because he was knock kneed. That one has just as much of an inferiority complex, but it is because his parents made him feel a failure when it transpired that he did not have when it transpired that he did not have the talent for mathematics which his older brother possessed, and was constantly bringing home from school low grades in that subject.

There is almost no limit to the possible points of origin of an inferiority complex

Once it becomes established, of course, it makes its possessor very uncomfortable. He reacts biologically by trying to get rid of this feeling—by trying to make himself more comfortable.

If he can not do this in conscious and useful ways, he will find some unconscious method of easing the situation. He may repress the whole thing in his mind, so that it no longer obtrudes itself on his attention. He may regress, that is, drop back to more childish ways of behaving, and try to get the consideration from others that he enjoyed when he was an infant and was not expected to accomplish much. He may day-dream, creating for himself an imaginary world in which he can rule as he likes—where he can select the most beautiful movie star as his queen, where he can turn everything into gold at a touch, where he can tell the boss just where to get off!

Characteristically, however, the victim of an inferiority complex attempts to escape from his discomfort by compensation—that is, by some sort of mental activity which will bring him feelings of personal worth not attainable in the usual way, and which will thereby enable him to "forget" his feelings of inferiority.

Three "attempts to compensate for an inferiority complex" have become traditional; they are immunerable and extra-ordinarily diverse in form; which one of them an individual unconsiciously selects will depend on his own background and personality. Among the best-recognized of them are the following:

1 Bluffing.

The boaster and the bully alike are open to suspection of trying to cover up their own feelings of inferiority. The test is to challenge them in the very field in which they profess particularly to excel if a man tells you that he has a grand opera voice, ask him to sing before a group. You will suddenly learn that he has a slight cold; or he needs his own special accompanist. The bully is notoriously ready to fight at the drop of a hat—but only with one smaller than himself. Equally noticious is it that the man who is constantly boasting of his sexual provess is likely, in fact, to be impotent.

Similarly the aggressive back-slapper who knows it all, who is never arguing but always just telling you, who laughs bloudest and talks most, who is blustering or snobbish as the case may be, and who is often supposed to have a superiority complex, is much more likely to be suffering from an inferiority complex, which he is trying to cover up.

2. Posing.

This is a little more subtle than the bluffing just described. It affords wide scope for the subject's imagination and his ability to dramatize himself.

Mr. W., for example, is a prophet. He is always predicting what will happen and he insists that you attach great importance to his telling you so. "Mark my words" is an injunction even dearer to him has been as to be a support of the construction of the mach more frequently. By dealing only in future events, he can avoid having to face realities. He can attract enough attention for his purpose by assuring the bystanders in the most solemn manner—and adjuring them particularly to remember that he warned them—that

America will have its first communist president in 1948. He knows that in the intervening ten years everyone will have forgotten him; but for the present he gets a minute's immersion in the grateful warmth of the limelight.

Mr. B., similarly motivated, is "an inventor." Nothing stands to his credit in the Patent Office, and his rent is often unpaid, but he continues to be mysterious—much as he trusts you. he dare not

"The greater a man is, the more likely he is to be modest and genusnely humble, as seen almost universally among the great men of science." Prof. Einstein, whose manner is utterly natural and simple entirely free from pose. With a wide variety of disputatious persons, many of them fanatical cranks in their bitter opposition (if not actually paranoids), trying for years to draw him into argument about his theories, he offers no battle, no resistance, simply letting his work stand or fall on its own merits and going his usual calm, peaceful way, smoking his pipe: he is not "on the defensive." Emotional maturity

confide even to you what he is working on: it might cost him his life. Meanwhile,

tt s at least a good alibi for laziness. Mr. G. credite himself with profundry, which he impresses on you delicately by talking over your head. He likes the words in the back of the dictionary, Of course you understand the "centre-stand-ive principle of procedurity". Not entire-by Well, that's too bad; but then, it's no use for him to try to explain—you wouldn't be able to follow the discussion.

And so on through an endless procession of posers, many of them not merely harmless but amiable, who help to entertain the world and fool no one except themselves. They are all trying to cover up their inferiority complexes by a show.

3. Passing it on to others.

If one feels inferior, he can always find

If one feels inferior, he can always find someone else whom he considers even more inferior and, by comparison, make himself feel quite a personage. Much race prejudice stems from this source. The "high yellow" Negro looks down on the ordinary mulate who in turn considers himself much superior to the black. Among Jews in America, those Mediterranean ancestry consider themselves socially superior to the German Jew who, in turn, does not like to accept the Russan Jew as an equal. 4. Rejorning others.

One who is trying to redeem people from their vices or sins can scarcely help feeling superior to the unfortunates whom he is uplifting. As he looks at the drunkard, the virtuous man may say, "There, but for the grace of God, go I"; but unconsciously he can scarcely help reflecting. "At any rate, I don't go there."

Moreover, psychologists generally agree that when a man shows a particularly strong emotional aversion to some
human frailiy, it is likely to mean that she himself has a strong unconscious tendency toward that frailiy. Zeal in retendency toward that frailiy. Zeal in reforming others may help to distract his attention from he own shortcomings and of
thereby enable him to live more at peace
with himself.

5. Rationalization.

This is the process of dressing up an unpalatable fact so that it becomes attractive. It as a common component of mental life. As the late old J. Pierpont Morgan once remarked: "A man always and so two reasons for doing anything—a good reason, and the real reason." Rationalization, or the process of finding "a good reason," is particularly employed to compensate for an inferiority complex.

The "sour grapes" attitude is proverbial. The "sweet lemons" attitude is merely another manifestation of it, exemplified by Pollyanna and more pretentiously by the old philosophy that "Whatever is, is right."

Mr O is afrad to marry. He is afraid of life, efrad of sex, afrad of himself Naturally, he won't confess these fears, even to himself; won't admit that he thinks no woman could be attracted to him, and that if she were he couldn't hold her. He will rationalize. He will continually prase marriage and explain that it is so important that he doesn't want to make any mistake when he marries. One shouldn't marry until one finds just the right girl. If you know Mr. O., you know that he will take great pains never to find the right girl.

A common and tiresome device of peohe common and tiresome device of peoparage themselves. Dickens' famous character, Urah Heep, was continually announcing that he was "the most 'umble person' that ever lived. The girl who is not sure of herself is incessantly reminding you that nobody loves her. The scientist with an inferiority complex asserts at every opportunity: "I know absolutely nothing about this subject."

Of course, all of them want merely to be contradicted. The bait is annoyingly

Uriah Heep and David Copperfield, "'Umble as I am," says Uriah to David

obvious. The girl wants to be told: "Who could help loving you?" The scientist wants to hear you say: "If I knew one tenth as much as you do about it, I'd be a wise man." They would be considerably disconcerted if you merely agreed with

7. Throwing up a cloud of dust.

Everyone knows Mr. L—the type of a business man who is always in a hurry, a lways "going through the motions." He always "going through the motions." He hasn't a moment to stop and talk with you because there are so many hig deals awaiting his attention at the office. While he is telling you about them and lamenting the tremendous pressure under which he lives, which doesn't permit him to stop a minute to pass the time of day with a friend, he has killed half an hour of your time.

Arriving at the office, he agas one letter while he is opening another, grabs but the telephone at the same moment that he lights a cigar, calls his stemographer before he takes off his overcost—and keeps her standing idly by while he he cleans out the drawers of his deak and the the good time they had at the club last night.

His room is littered with Work-Organizers, Time-Treasurers, Fact-Finders, Future-Filers, Appointment-Announcers, System-Establishers, Ready-Reckoners, Second-Savers, Minute-Makers, and Efficiency-Increasers.

The general result of this pressure of activity is the same as that obtained by a small boy when he puts the gears of his father's automobile in neutral and then steps on the accelerator. The car doesn't go anywhere, but it does produce a very satisfying lot of noise and vibration.

This pressure of activity, which throws up a cloud of dust in which no one can see just what the thrower is accomplishing, is a common way of covering up a feeling of inefficiency, inadequacy, and inferiority.

Hitching your wagon to a star.
 One of the most "high-toned" ways to avoid competition and to escape the possibility of defeat is to adopt some lofty and unattainable goal.

Prof. M. has been working for 20 years on some sort of chemical process. No one except himself knows quite what it is, but everyone knows that it is very important -definitely fundamental, in fact. He has actually done an immense amount of routine work. He assures you that he isn't the man to "rush into print" with a half-baked announcement; he is going to publish as soon as he has really completed the 10b. Since it is humanly impossible to complete such a job, he will die unpublished; meanwhile he has more of a reputation than he deserves because people take his hints seriously and don't know that this pose of profundity merely serves as a cover for aimlessness and futility.

Miss F. is going to marry as soon as she finds the right man. The man who gets her will have to be a good man. In fact, he will have to combine in one person all the best qualities of Robert Tay. Or, Edsel Ford, Max Schneling, Glenn Frank, Henry Cabot Lodge, Gary Coper, and Nelson Eddy. Since few of us mere males can attain such a composite standard of excellence (though of course most of us come very close to it), Miss F. will unquestionably die unmarriable than the composite will unquestionably die unmarriable.

This device of setting up a fictitious and unattainable goal is a particularly good one because it seems to denote a lofty spirit, and because of course there is much truth in the idea that "Not failure, but low aim, is crime," and so on, as poets and philosophers have remarked

at great length. But the goal should be at least reasonably realistic. While one man is "standing by," waiting for a chance to get a hitch on to a star, another has hitched his wagon to a tractor and accomplished a good day's work.

All these compensatory mechanism, and others that will occur to the reader's mind, help to make life interesting. Few of us can pretend to have avoided them altogether. But when they lead toward false goals, when they prevent worthwhile achievement, when they merely reflect inadequate personalities, they need attention.

The practical question, then, is: What can be done with an inferiority complex?

1. Recognize your disabilities

Don't try to fool yourself. Unfortunately, it is much easier to fool yourself than to fool others. They can see you plainly because they don't look at you through an emotional fog as you look at yourself.

It's just as great a mistake to exaggerate your disabilities as to depreciate them. Expert appraisal by a disinterested person will often help you to correct the perspective.

In the case of mental qualities, emotional attributes, special talents, and professional aptitudes, the use of some of the modern batteries of tests may be a great help. No one pretends that they are micrometrically accurate, but they are good rough and ready measurements in the hands of one who has the training and experience to interpret them. Measurements of this sort should be given to every young person, as a routine procedure, somewhere in the high school period. They would help boys and girls to find their places in the world without too great a tendency either to over-value or to under-value themselves. They would keep square pegs out of round holes.

keep square pegs out of round holes.

2. Overcome your disabilities if possible.

The process of doing so is often the road to achievement. The elder Theodore Roosevelt was a num boy, by deserming.

Reacted was a puny boy; by determinaReacted was a puny boy; by determinaReacted was a puny boy; by determination of the control of the control of the
veloped into the capit handed the and developed into the capit handed the and
veloped into the capit handed the and
possible. The description of the story of Demosthenes overcoming his
speech impediment by talking with pebbles in his mouth, and developing into
the greatest orator of his time, neay not
have much historical basis, but it is at
east symbolic of what many another has
accomplished under the stimulus of a
will to overcome.

 If you can't overcome a handicap, act as if you didn't have it. As Beethoven became deaf, he worked with more and more industry at his musical composition, turning out better and better work.

Finally, develop your strong points.
 Find out what you can do successfully, and do it

Staticless Radio

Invention Opens Up New Uses for the High Frequency Channels . . . Receiver Automatically Rejects Static Impulses

EDITON'S NOTE: The radio system described below is for use on the short waves only and cannot be adapted to the standard broadcasting waves.

THE first high-powered, staticless radio station in the world employing a "frequency-modulated" system of transmission and reception, will be put into scheduled operation early this year, with the call letters W2XMN, it is announced by Major Edwin H. Armstrong, professor of electrical enginering in Columbia University, who designed and built the broadcasting equipment.

The new system will use an invention of Major Armstrong's which wipes out static, tube noises, and interference. It will greatly relieve the danger of the are waves being monopolized, which has given so much concern to Congress, by making possible a service on the ultrahigh frequency channels that are comparatively unused at present.

Construction of frequency-modulated receiving sets of the new type has already been started on a commercial basis by General Electric. The new sets, when produced on a quantity hasis, will cost no more than the ordinary good set of today and will be able to receive both the old and the new kinds of broadcasting much the same as sets now receive both the short- and long-wave programs.

Station W2XMN, built in a wooded section of Alpine, New Jersey, atop the Palisades, has a 400-foot tower with three 150-foot crossarms. The aerial consists of a series of copper plated steel bars fastened to a boom suspended between the tower's crossarms. The adjustment of this antenna proved to be the most difficult part of the whole construction. For a period of two months last summer Major Armstrong sat in a boatswain's chair several hours a day, 400 feet up, regulating the transmission lines. "As this had to be done with the power on; the combination of dodging the high voltage and the frequent thunder storms made the day's work always an interesting one," Major Armstrong said.

Two similar stations, built on an experimental scale, are in existence, one in Albany, New York, owned by General Electric, and the other at Storts, Connecticut, erected by Professor Daniel Noble of Connecticut State College. Six other stations are being constructed in the cast.

W2XMN is at present licensed by the Federal Communications Commission to broadcast in the vicinity of 40 megacycles, which corresponds to a wavelength of about seven meters. While this is an ex-

tremely short wavelength judged by ordinary broadcasting standards, the invention can be used equally effectively on still shorter wavelengths.

The new frequency modulation differfrom the amplitude modulated transmitter now in use in that the frequency broadcast by the improved method is changed in accordance with the fluctuations of the voice, and not the intensity of the radiation, as in the existing amplitude modulation method of broadcasting.

FREQUENCY modulation programs, at any given listening point within the range of the station, will, in general, have from one one-hundaredth to one moethousandth the disturbance of programs broadcast by the present method, it is claimed. This means much better reception within the service area for the mew station, conservatively estimated at 100 miles. The receiver automatically rejects a signal that is too weak to be received satisfactorily, such as man-made or natural static noises, but receives all waves sent out from the high-powered transmitter.

In addition to the advantages in sound production, it is said that the method

The tower of W2XMN, designed for use with the new Armstrong staticless radio system

can be used for multiplex sending, and that sa many a four programs have been simultaneously transmitted and received by one transmitter and one receiver. The theory on which the system works is a direct reversal of that on which engineers have previously worked to eliminate noises. The old principle has been to narrow down extraneous sounds, while the Armstrong system does not consider the proposite. It is this necessity for a wide band which rankes the new system impractical on the wavelengths now customarily used for ordinary broadcasting.

When the invention was demonstrated before the Institute of Radio Engineers. a sound-reel recording was played, comparing the reception during a thunder storm of the old and new types of broadcasting. The recording was made from broadcasts received at a distance of 85 miles from a two-kilowatt frequencymodulated station, and from WEAF, a 50-kilowatt station. While WEAF came through strongly, its program was sometimes unintelligible because of crashes of static. In contrast, the frequencymodulated signals provided an uninterrupted, clear program, free from static, despite the fact that its power was only 4 percent of that of the larger station.

THEN an automobile manufacturer wants to know whether the springing of his new model is adequate, or the radiator large enough, he does not have the car driven over smooth concrete roads. He puts it in charge of a test driver who "gives it the works," as it were, by taking it over rough country and making it do all manner of things an ordinary driver would never

Similarly, in scientific research, much more can be found out about the way materials behave, and the way molecules behave, if they are tested in unusual circumstances. Sometimes high temperatures are used, or strong electric fields, or high pressures, or very low temperatures. It is with the last that we are concerned here.

When scientists write about low temperature research, they are thinking of temperatures about 450 degrees below zero Fahrenheit, or about -270 degrees centigrade. In some of his experiments, the scientist tries to reach as low a temperature as possible, and it is at least comforting to know that there is a natural limit of temperature beyond which he cannot go, and which represents the greatest degree of cold attainable, or even imaginable. This absolute zero is at 273 degrees below zero centigrade. Nothing has ever been quite as

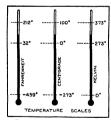

Figure 1: Three temperature scales the Kelvin being the most logical

cold as this, but very nearly, within a few hundredths of a degree, in fact, But those last few hundredths are the hardest ones to surmount A temperature of -275 degrees C. not only has never been attained, but it is just as much a contradiction in terms as a square circle or a wooden piece of steel. To make the numbers smaller, temperatures are often reckoned from the absolute zero as a starting point, and when this is done, the Kelvin scale results (Figure 1). Thus a temperature of 4 degrees K. is

THE CURIOUS CASE

Wherein a Liquid is Discovered to Behave like a Cat-footed Burglar and to Puzzle Scientists by its Extraordinary Fluidity . . . Still Is a Puzzle

the same as -269 degrees C., and the boiling point of water, 100 degrees C., is the same as 373 degrees K.

Everything is frozen solid at temperatures below 14 degrees K., except helium, the light gas that is used in airships. Hydrogen, the next best thing, melts at 14 degrees K, and boils away to hydrogen gas at 20 degrees K. Liquid air is really hot-it freezes at 55 degrees K. and boils at 91 degrees K. All these cold substances, of course, must be kept in double-walled Thermos bottles.

Low temperature research is complicated and expensive. Only a few laboratories are well equipped for it. The most notable on this continent is at the University of Toronto, where Professor Burton and his colleagues make about a quart of liquid helium weekly,

IQUID helium boils at 4.2 degrees K., ■ at atmospheric pressure. If the boiling is quickened by pumping off the gas, the increased evaporation lowers the temperature gradually. Meanwhile the liquid boils vigorously. All of a sudden, at 219 degrees K., the liquid seems to stop boiling; at least it is quiet, but evaporation continues, as shown by the gas which can be pumped off, and the temperature keeps on falling. This observation is merely one of many which show that the temperature, 2.19 degrees K., marks a transition point between two states of helium. For want of better names they are called helium I and helium II. Helium I is the warmer. helium II the colder. The name λ-point (Greek, lambda) is given to this transition temperature.

Even its most prosaic properties make liquid helium a remarkable fluid. We think of water as a typical liquid-a quart of it weighs just over 2 pounds. A quart of liquid helium would weigh only about 5 ounces, just 3/20 as much as water. It has been known for some time that helium II possesses an unusual heat conducting capacity far in excess of helium I, and some time ago Professor Kapitza thought this might be due to an abnormally high fluidity-or low viscosity, as the physicists call it. This would mean that the liquid would circulate with extreme ease, carrying heat by means of convection currents.

Peter Kapitza will be remembered as a Russian scientist who spent many years in Lord Rutherford's laboratory at Cambridge, England, First he was interested in producing very strong magnetic fields, which he accomplished successfully. Then he turned his attention to research at low temperatures, among other things, and a special laboratory was constructed for him, complete with helium liquefier [described in Scientific American, December, 1934, pages 300-302.—Ed.]. Then, suddenly, while he was on a holiday in the U.S.S.R., the government apparently declined to let him leave, but offered him adequate facilities for pursuing his work in Moscow, The difficulty then was to know what to do with his new equipment in Cambridge. for a scientist's own research equipment, minus the scientist, is rather like a ship without a rudder or engines. Finally some of the equipment was purchased by the U.S.S.R. for Kapitza's use, and his friends were pleased to see in Nature. a little more than a year ago, a letter recording some of his experiments.

Kapitza, then, set out to measure the fluidity or viscosity of helium II. The usual commercial methods, or even the usual laboratory methods, were not very convenient at 2 degrees K., so he devised the following scheme. A tube (A, Figure 2, left), had fixed to its lower end a heavy glass plate B, with a hole through the middle. Below this was another plate C. whose distance from B could be varied by devices that the diagram does not show. The inner surfaces between B and C were optically flat. Then B and C

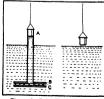

Figure 2: Left: Kapitsa's experiment. Right: The suspended beaker

of Liquid Helium

By THOMAS H. OSGOOD, M.S., Ph.D. Head of the Department of Physics at the University of Toledo

were fixed at a convenient distance apart -let us say 1/32 inch-and the whole thing was lowered into a bath of liquid helium II. Soon, the two levels, inside and outside the tube, were the same. Now for the experiment. The unit was quickly raised a short distance, making the level inside A higher than outside. This inner level was expected gradually to fall, as the liquid leaked out between R and C. But it fell faster than was expected. In another case B and C were placed in optical contact, meaning that they were pressed firmly together. You would think that the helium II inside could now hardly escape. But you are wrong. The inner level of liquid settled down in a few seconds. Here was a curious liquid, one that could slip in a few seconds through a space about a thousandth as wide as the thickness of a sheet of paper!! Indeed, in all the previous history of physics, no substance ever before displayed such remarkable fluidity; upon calculation, this helium II, a liquid, turned out to be about 10,000 times as easy flowing as hydrogen gas. It sounds almost incredible. But how to find out the truth?

THE next step is an obvious one, THE next step is an owner. If he once it has been pointed out. If he lium II can slide through cracks as easily as Kapitza's experiment showed, surely it is worth while trying to see whether it can slide through no crack at all. A report of experiments of this kind was published in the middle of 1938 by Daunt and Mendelssohn of the Clarendon Laboratory, Oxford, England, but they were careful to point out that their experiments were merely an elaboration of an observation of Kammerlingh Onnes of Leiden (in 1922) that the surfaces of two volumes of liquid helium II in two concentric vessels, adjusted themselves automatically to the same level. Daunt and Mendelssohn suspended a tiny glass beaker (Figure 2, right) by a fine fiber so that it could be lowered into or raised from a bath of helium II. Here are their own words to describe the effects. "When the empty beaker was lowered into the liquid, it filled up to the level of the bath, although the rim of the heaker was everywhere above the level of the liquid. When the beaker was partly lifted out of the bath, the level of the liquid in the beaker fell . . . and the level of the bath rose until both had reached the same height. In order to establish whether the trans fer took place by distillation . . . or by transfer over the surface, the effect was examined of introducing wicks of twisted copper wire which increased the surface leading from one level to the other. It was found that this increased the rate of transfer to several times the previous rate so long as, but only so long as, the wick reached into the liquid at the higher level. When the beaker (without a

Figure 3: Apparatus for making li-quid helium, University of Toronto

wick) was completely lifted out of the bath, it was found that the liquid vanished at the same rate as when it was still partly dipping into it. This was accounted for when it was observed that the liquid collected in drops at the bottom of the beaker and dripped into the bath. The rate of transfer did not appear to differ very greatly whether the beaker was almost full or nearly empty." And the authors add, in conclusion: "If any of these phenomena occur above the \(\lambda\)-point (that is, with helium I) the rate is so slow that they could not be observed in our experimente "

Thus it seems clear that the surface of a solid in contact with helium II is covered with a helium film which transports the liquid to the lowest available level, and that the helium II creeps over the cold surface in an uncanny way. No wonder Kapitza was misled in the interpretation of his experiments! What happened, of course, was not that the helium II slipped through the crevice between plates B and C of Figure 2, left, but that the levels were equalized by the liquid creeping over the top of the open tube A. Perhaps "creep hardly the right word, for the moving film of helium is so thin that it must move at a speed about equal to that possessed by the molecules themselves a few hundred meters per second, that is, several hundred miles an hour,

LATER experiments in several labora-tories, especially at Toronto, have shown that the fluidity or viscosity of helium II is not nearly as low as Kapitza suggested. It turns out to be about the same as for gaseous hydrogen. But this in itself is low enough to set the theoretical physicists to work to try to explain why the helium II has these superfluid properties. The theories which are being proposed make the assumption that helium II is a sort of a cross between a gas and a liquid-a degenerate Einstein-Bose gas, to use the technical term. The problem is essentially this: In a gas, the molecules are, to all intents and purposes, quite independent of one another; the only thing that restricts them is the solid wall of a container, such as the shell of an oxygen tank which keeps in the oxygen. But open the valve, and out the oxygen rushes. On the other hand, the molecules in a liquid always stay at about the same distance apart. If you like a crude picture, you might say that the molecules are somehow hooked on to one another, by hooks which do not stretch. If you open a bottle of medicine, the medicine does not suddenly rush out into the room like the oxygen from the tank. In the case of helium II, then, the helium molecules must be attached to their neighbors by non-stretchable hooks, for the substance is a liquid. But at the same time, it can not have its extraordinarily low viscosity unless the molecules can slide past one another with the greatest of ease. This means that they must be able to change neighbors very readily. The question is, therefore, what kind of "hooks" do these molecules have which are firm enough not to stretch, and vet which automatically couple and uncouple their neighbors, but do not let those neighbors go free?

The "hooks" of which we speak must necessarily be electrical forces. Whether or not the theoretical physicists are on the right track, time and further experiments alone will tell. But when it is known how these "hooks" work, a new discovery will have been made about molecular forces.

The attractive result, a gleaming and lustrous string of matched natural pearls, one of the finest of its kind now on sale by jewelers in this country

The lovely natural pearl has been for countless centuries the subject of speculation in fable, song, and story. The only gem that comes from the sea, and the only one made by a living process, it aroused long ago the intense interest of those who were able to use only their imaginations to conceive of its origin and characteristics.

Now, however, thanks to the advances of science, we can study this most interesting of all gems with a thoroughness that might have amazed its early admirers.

In a recent article in Scientific American we discussed the attempts that have been made by man to simulate the natural pearl, which nature alone can fashion. Despite the ingenuity of man and the wonders of science, no artificial or "cultured" pearl can be produced that can compare with that warm, rose-colored bit of loveliness from the Persian Gulf that is the handiwork of an inspired Mother Nature. And although cultured and imitation pearls are available, they bear a similar relationship to the natural pearl as gold-filled articles do to solid gold jewelry, silver plate to sterling, or reproductions to genuine old masters

The entirely natural formation of the genuine Oriental pearl occurs, for example, where by chance a thing grain of sand or other foreign particle enters an oyster shell, or where some abnormal condition results in the growth of a pearl.

This tiny particle becomes the nucleus of the gem. Layer upon layer of nacre is deposited upon this heart as the pearl grows. These films that form the pearl vary in thickness, being much thinner

Science Dissects

By A. E. ALEXANDER, Ph.D. Pearl Fellowship, Mellon Institute, Pittsburgh, Pa

than a sheet of tissue paper. The most lustrous pearls are those in which the constituent layers are the thinnest, while those of less attractive appearance are made up of thicker and coarser layers of nacre.

of nacre.

We have authority for believing that the pearl generally takes its color from the shell lining, and even from that part of the shell near which it is formed. A rose- or cream-colored pearl would not be expected, according to this explanation, in an oyster in which the shell lining is of any other color.

Pearls may be rose, cream, white, grey, horne, black, pastel shades of lavender, blue, yellow, mauve, orange, krown, or green; but the more desirable colors are rose, cream, white, and black. The temperature and composition of the water and the state of health of the oyster are thought to determine the color of any given pearl. The appealing iridescence for which pearls are prizel is due primarily to the reflection and refraction of light which take place on the surface of the gem.

THE beauty and splendor of the pearl have been sung in the sacred books of the Christians, the Hebrews, and other religions. St. Matthew, for example, had a high appreciation of this gem: "The Kingdom of Heaven is like unto a merchant man seeking goodly pearls, who when he had found one pearl of great price, went and sold all that he had and bought it."

The gates of the Holy City were described as 12 pearls by St. John in the Book of Revelations. In the Talmud there is a reference to the pearl "that has no price," and also to manna that was "as white as pearl."

Hindu legend attributes the discovery of the pear lo Krishna, the form in which the preserving god Vishnu appeared in all his glory. According to this tale, took the pear I from the depths of the ocean to adorn his daughter on her wedding day. This is the source of the tradition that links pearls to brides even to the present.

In the classical period of Sanskrit literature, about the 3rd Century of the Christian era, there were abundant references to the pearl. It was generally called "mutka," the pure, and there were numerous words for pearl bracelets, necklaces, and other pearl ornaments in the dramas of Kalidasa, the Hindu Shakespeare.

According to "The Kingdom of the Pearl," by Leonard Rosenthal, it is be-leved that pearls were the first gens known to man. It is lakely that the discovery of the pearl was made by some member of a fish-eating trube on the shores of India. The Ancient was possibly attracted by the brilliance of the gen when he opened the mollusks that were intended for his food. As his natural taste for beauty developed, he used it to satisfy his desert for adornment, which characterizes alike the most primitive tribes and the most refined civilizations.

The Chinese knew and appreciated the pearl at a very early date. The gens were accepted by them in payment of tribute. Some fantastic Chinese tales tell about pearls so brilliant that their glow could cook rice a thousand miles away. And about the beginning of the Christian Era it was reported that one pearl was found so lustrous that it could be seen in the dark at a distance of three miles!

The tale of Cleopatra drinking wine in which she had dissolved a pearl from an earring is known to every student of legend. Science, however, must modify the story by pointing out that a pearl cannot be readily dissolved in sour wine unless it is first powdered.

But there is record in subsequent history of the drinking of a valuable pearl. During the reign of Queen Elizabeth, Sir Thomas Gresham, who possessed a famous pearl worth 15,000 pounds, ground it to a powder, and drank it to his sovereign's health when he was entertaining the Spanish ambassador at dinner. His purpose was to show the Spanish of what luxury the English were capable; and probably, also, to prove that England had the wealth to raise a fleet to protect herself!

Catherine de Medici owned the most exquisite pearls in the world, according to the historian Bapts, when in 1533 she married Henry, Duke of Orleans, afterward Henry II of France. She had two large pear-shaped pearls weighing about 92 grains each, which were presented to her by Francis I, and which she later gave to Mary Stuart.

Of the very large pearls generally mentioned by writers, three undoubtedly exist: La Pellegrina, the Beresford Hope.

THE PEARL

Oldest Gem Gives Up Its Secrets . . . How and Why Make-Up Varies . . . Iridescence . . . Nucleus Usually Absent . . . Microscope, X Ray, Other Tools Used

and one of medium quality in the Austrian crown weighing about 1200 grains. The finest is La Pellegrina, which is perfectly round and so lustrous that it appears to be transparent.

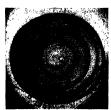

For many centuries the finest pearls in the world have come from the Persana Gulf, chiefly from the waters around the Island of Bahrein Here, most of the population depends for livelihood upon pearl fishing, according to a British writer, on whose recent account some of the material in the next few paragraphs is based. Some 75,000 natives depend for their living on pearl diving, as have their ancestors for nearly 2000 years.

The present ruler of the tuny independency is Shakh Hamad bin Isa al Khalifah, a member of an ancient Arab family which came originally from the manland of Arabia. Though he encurages modern methods and improvements, he lives as an Arab Shaikh, always wearing the dress of ha country, surrounded by picturesque retainers, and spends much of his spare time in bunting, coursing with Saluki hounds, and in hawking.

Although the richest pearl banks in the world are around Bahrian, the Shakh receives no direct income from pearls. The revenue of his state is mainly derived from customs duties upon imports and from oil royalties. The value of importations, however, depends upon the success of the diving season, which lasts from the middle of May until the end of September, while the water is ware.

On a day appointed by the Shaikh, which is announced by public proclamation, the pearling fleet, consisting of several hundred sailing dhows, very like

Roman galleys, sets out from Bahren to the pearling banks. Until they clear harhor, the boats are propelled by heavy oars, each pulled by two men, who sing the song of the pearlers as they row. Often the fleet returns at night when the moon and tide are full. The sound of the sallors chanting and the sight of bunfreds of white sails colored orange by the

Section of a typical Oriental saltwater pearl, showing concentric arrangement of mineral matter throughout. An ideal pearl, structurally, Magnified about seven times

light of fires burning on the decks is, indeed, very picturesque.

The pearl divers use no mechanical apparatus of any kind, and the diving methods have changed little since they were first described by 14bb-Century travelers. Each diver wears a clip like, a clothespin over his nose, and leather sheaths to protect his fingers and to enable him to wrench the shells from trocks underneath the sea. Each of his big

toes is guarded by a similar abeath. Grasping a stone as a weight, he descends on a rope to the bottom. Around his neck is a string bag, which he fills as rapidly as he can during the minute and a half he is able to stay under water. When the air in his lungs is exhausted, he gives the signal, and is pulled up to the surface by his companion in the boat. A good diver can descend about 30 times in a day, often to a depth of 14 fathoms.

The shells are piled on dock to be opened later under the watchful eye of the captam, who carefully guards the pearl treasure in a chest. The shells are thrown back into the sea, for the divers believe that oysters feed on them. They believe, too, that the pearls are formed by drops of dew that fall into the oysters at night!

The men receive no regular wages, but share in the profits of the boat to which they are attached. The general principle of the diving system is fair, especially sance the present. Shash delegates government employees to check on the books kept of the season's catch. A certain percentage of the crew, chosen by the men of each boat, must writness the sale of the pearls by the captain to satisfy themselves that they receive a proper share of the profits.

WHEN sold, the pearls go from Bahrein to the great markets of India. Here steps are taken to bring out their sublime luster. Each jewel is carrefully washed and polished by expert workmen. Next, the pearls that are to be used in necklaces must be drilled by hand. The skilled craftsmen in charge of this step employ a delicate method of drilling that has not changed in 3000 water.

In India, the gleaming finished pearls are purchased by dealers who take them to Paris or London. To these pearl centers, buyers from this side of the Atlantic travel to select their stocks.

Interesting as may be the facts we have discovered, the scientist must delve still deeper into the physical characteristics of the pearl. Science must view not only the surface, but must go beneath it.

The best way to seek out the story behind the pearl is to examine its internal structure microscopically. To do

An ideal "Maltese cross" X-ray diffraction pattern (two exposures) produced from a cultured pearl of 7.36 grains

Two characteristic diffraction patterns produced from a natural pearl (7.44 grains) with fine concentric layers

this, one must thin-section the lewel. A pearl to be thin-sectioned is first ground on a coarse diamond lap or polishing surface until its maximum diameter has been reached. A few turns over a finer textured diamond lap will eliminate the scratches produced by the previous grinding operation. The pearl is next cemented to a microscope object glass, using Canada balsam. After the balsam has hardened, the remainder of the pearl is ground to wafer thinness, first on a coarse diamond lap and finally to a thickness of 0.03 millimeter on a lap of very fine grain. A cover glass is cemented over the specimen and the thin-sectioned pearl is now ready for microscopic examination

The optical properties of the mineral matter are best observed using polarized light. From such a thin-section one finds that a natural pearl is, in general, structurally not unlike an onion, in that the numerous layers of mineral matter are concentrically deposited from the innermost part of the jewel to the exterior Because of this interesting structural arrangement, a pearl can be "skinned" very much as an onion can be peeled.

CHEMICALLY, the pearl is composed almost entirely of calcium earboaste. This material, on examination, is found to be deposited around a tenuous network of organic matter, which has been termed conclubilit, much like the enamel around marble are composed of the hexagonal warety of calcium carbonate, calette. Few pearls have this mineral in their constitution. The form most generally present in pearl substance is the orthorhombic warety of calcium carbonate, cargonite.

The gem, exquisite as it is, is in a sense an abnormal growth. Unlike other concretions and pathologic products in ani-

mal and vegetable life, however, it is strikingly beautiful in its evidence of disordered physologic change. In the case of the pearl-oyster, some irritation is presumed to have been set up in the microscopic irritant, if from an external source, may have been of organic origin —perhaps some species of trematode or, again, it may have been inorganic in character, as for example, a grain of and or an agglomerate of silt. The mollusk, unable to rid itself of the unwelcome intruder, seeks to reduce the attendant urritation by coating the substance with nacrooss materials.

Certain epithelial cells within the mantle of the oyster have the ability to extract from the sea water those salts necessary to produce calcium carbonate. It has been stated that it is not temperature that controls the crystallization of calcite and argonite so much as it is the acidity or alkalinity of the carbonate solution. Calcite crystallizes from an acid solution while aragonate forms under alkalue conductures.

The interior of some natural pearls has been found, in instances within the writer's experience, to consist of coarse-ly crystallane calcite around which have been deposited concentric layers of aragonite. In the case of this particular, pearl, then, the physiological state was such that only calcite could be deposited in the beginning. Later, the physiological-chemical processes of the pearl-voster changed to the extent that alkalinity prevailed and calcium carbonate in the form of aragonite was laid down

Many natural pearls, when sectioned, reveal no evidence whatever of an irritant. From this observation we must assume that the nucleus has been of organic nature or perhaps of internal origin. Shortly after deposition began,

decomposition of the organic matter ensued, with the result that the final product reveals no evidence of what initiated the process.

To look further into the subject of iridescence, we must call on the principles of optics, in order to explain how light acts on transparent and translucent substances in thun films. Light entering a medium, unless the latter is amorphous

A natural salt-water pearl possessing a central area composed of radiating crystals of calcite, around which have been deposited concentrically arranged layers of aragonite

in character, will deviate from its normal course. The beam reacting in this manner is said to be refracted. If light is directed on an object from an angle, a certain amount will be cast back into the eyes of the observer. This light has been totally reflected. On microscopic examination, using polarized light, the concentric laminae of natural pearl substance-viz, aragonite-are found to lie in a basal plane; that is, in a plane perpendicular to the vertical crystallographic axis. These laminae are exceedingly thin and tenuous, Furthermore, they overlap one another. Their edges. when examined closely, resemble to a marked degree certain contour lines seen on topographic maps, which are used to designate rough and rugged country. The surface of a pearl, when examined microscopically, may not be entirely smooth in some cases. In fact, it may have a hammered appearance, not unlike that seen on hand-wrought copper.

The modern trend toward specialization has reached the jewelry field, and the handling of pearls has become a definite specially, Just as a dealer in fine paintings or rare antiques devotes his life to the study of these works of art, to so does the pearl expert develop his skill to an uncanny degree in identifying and valuating pearls. Not only have many of these specialists gained the ability to distinguish by the naked eye between a genuine pearl and a "cultured" product, but they can also tell by visual recognition the geographical region in which a pearl originated.

In addition to the identifying work of

The deck partner of a pearl diver is holding the small string bag which the diver fills in a quick descent. Oysters are accumulated and are not opened until the end of the pearling day

gem experts, however, there are definite scentific tests by which the exact differences between genuine peals and their smulations can be made a matter of precedence when the genuine the second secretary have devised over a period of years, and lar now in more or less active use. Each procedure will now be considered smulately

the of the simplest methods of disinguishing between natural and siralled "cultured" pearls is the accurate determination of their specific gravity. The crassest means of making this test is to animetsing them in liquids of known density. The procedure usually consists to placing a pearl in a small container partially filled with acception tetrahronid, to which orthodichloodwarene is added drop by drop until the pearl is in small container and the liquid then may be considered who may be considered when the may be considered who may be considered who may be considered who may be considered when the may be considered when the may be considered who may be considered when the m

The specific gravity of the liquid is not obtained by means of the Westphal balance. The heaviest cultured pearl examined by the writer had a specific gravity of 2805; the lightest, 2715 Natural pearls have a lower specific gravity, averaging 2.665. The test, however, has its huntations

For the past 15 years, the X-ray has been used to differentiate natural from cultured pearls. This procedure is accomplished by passing a narrow beam of X-rays through a metallic lead pinhole

Natural pearl, of an unusual shape, showing concentric layers extending throughout. Photographed in polarized light. No nucleus present; central spot is an optical effect

cantera" of proper thickness, having an other 0.02 or 0.94 of an inch in diameter. The pearl to be tested is placed over the small opening through which the X-ray beam is to pass. If the gen is natural, a uniform scattering of the X rays takes place when they unpunge, and, therefore, they will produce upon a photographic plate a six or twelve-fold "spot" pat-tern. This characteristic pattern is caused by the regular concentre arrangement of the aragonite characteristic of natural saltwater pearls.

A cultured pearl similarly tested, on

Pearl divers are rugged, with extraordinarily well-developed lungs. This man is ready to dive and holds the rope by which his partner, on deck, will pull him up from the depths

the other hand, will usually produce a maltese cross pattern, or modification thereof; this appearance is attributable to the peculiar parallel mineral arrangement found in all mother-of pearl sub-

Another ingenious method used to differentiate cultured pearls from the strial gens employs an "Embosope," invented by Chilowsky and Perrin in 1926 Brieft, the apparatus consests of a carbon are a lens system, and a hollow hypodermicals he needle, at the tip of which are placed two platinum mirrors set at angles of \$5 degrees and in opposite directions from one another.

As a typical natural pearl is composed of concentrically deposited aragonite throughout, and a cultured pearl has a large core that is distinctly layered, it is plain that light directed within such structures should react differently because of their physical differences. If a drilled natural salt-water pearl is placed on the hypodermic-like needle and then observed through the focusing eveniece of the lens system, one finds that a flash is produced when the pearl is moved back and forth over the needle after the are has started to burn. A similar test made on a cultured pearl will not reveal this flash. In the former case, the powerful beam of light traversing the needle is reflected from the first minute platinum mirror up to the pearl substance. Because the layers are concentrically arranged throughout, the light is totally reflected. On moving the pearl back and forth, the totally reflected light is "caught" or reflected on the second or outside mirror which constitutes the tip of the needle. The registered flash is seen in the evepiece. A cultured pearl, having a large core composed of parallel layers, will not reflect light and, consequently, no flash is produced.

By this method only one drilled pearl

can be examined at a time. Furthermore, this test cannot be applied to undrilled terms.

All numeral matter is either diamagnetic from leading of this physical property resulted in the inventor of a new instrument by Pr. Richard Nacken, of Germany, in 1929. The structural differences in pearls mentioned in the preceding paragraph permits differentiation by the use of this method. The test, however, is not as efficient as the endoscopic procedure, and is the least used.

FOR many generations distinguished families have considered pairls as heriform gens, to be handed down from mother to daughter, usually on the welding day. We have seen how this linking of pairls with bride goos far back into history, beginning with early Indian legends. Lake thests of sibrer, pearls never go out of style, nor does their value decrease with the generations.

There is a definite reason for this permanent value. Unlike other pewels there is no need for a "world corner" on the pearl market. The number of really fine pearls brought up in any one year is definitely limited No great "find" even definitely limited No great "find" even necessary to hold up part of any year's outnot.

It may take years—in fact, it nearly always does—to assemble a superb necklace. When, therefore, the pearls are finally brought together into a matched string, the achievement is eventful, and their value in this form is greater together than their combined separate cost

It is evident from what has been said that the popularity of the pearl is in no sence faddish. With 4000 years of admiration behind it, this beauteous gern may look forward to as many in the future

Inside The Stars

S OME of the simplest-sounding questions are the hardest to answer. We know a good deal about the stars by this time—their distances, their motion, their real hightness, and, in many cases, their actual diameters, but it has taken a long time to answer, even in part, the obvious question, "Why do the stars-sime?"

In one sense, the answer is casy enough. The stars shine because they are hot--very hot indeed, even in their outermost atmospheres. Unless the whole surface of a star is as hot as the hottest part of a blast furnace, it will not shine brightly enough to be visible at the enormous distances with which we have to deal. We can measure this surface temperature by methods similar in principle to those which are used to find the temperature of an industrial furnace-by the intensity and color of the light which comes out through a hole in the door--and we find that, for a red star (cool as stars go) it is from 2000 to 3000 degrees, centigrade, The Sun's is 5700 degrees, and the figure rises to some 10,000 degrees for white stars like Strius, over 20,000 degrees for the stars in Orion's belt, and perhaps 50,000 degrees for the very hottest stars,

We can calculate just how bright a star of given size and temperature will look at a distance of so many light-years, but this does not answer the question "What makes the stars so hot?" Here again we may "stall along" with a simple answer. The stars are hot outside because they are still hotter inside, and the heat leaks out to the surface, But the questioner might reply, "You can't get inside a star to find out about it, how do you know that it is hot inside?" And the answer comes: It has got to be enormously hot insidemillions of degrees-provided only that the matter of which it is composed is of the same nature as that which we can study in our laboratories, and there is plenty of good evidence to convince us that this is true.

From the Sun's gravitational attraction on the planets, we can find its total mass, and that its average density is 14 times that of water. Its attraction upon its own outer layers produces an enormous internal pressure. If the density was same at all pounts, the pressure at the center (as can easily be calculated) would be 98,000,000 tons per square inch.

It is no more than a high-school exercise to calculate how hot a mass of gas would be if this enormous pressure compressed it to no more than the given density—provided that one assumes that Why do the Stars Shine, How do We Know They Are So Exceedingly Hot inside, and What Makes them So? From Whence Comes their Vast Store of Energy?

By HENRY NORRIS RUSSELL, Ph.D.

Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Mount Wilson Observatory of the Carnegic Institution of Washington

the familiar "gas laws" of the laboratory can be applied under these extreme conditions. If the gas was hydrogen (loose atoms, not molecules) the temperature would be 11,500,000 degrees, centigrade.

It is of course practically certain that the density is greater at the center than the average, and probable that it is much greater, and to get an exact value we would have to know just how the density varied at different distances from the center. But to increase the central density means to bring the material nearer the center, and give gravity a more powerful hold on it, and this increases the pressure Calculations made for different "models" show that these two changes nearly compensate one another. For example, a density-model which Eddington has made famous has a central density 54 times the mean; the pressure is increased 92 times. but the ratio of the two, and hence the temperature, is increased only in the ratio 1 70. Another model, recently calculated by Chandrasekhar, makes the central density 88 times and the pressure 171 times the values first considered; the factor for the temperature is 195.

THE temperature at the Sun's center, on these two models, comes out 19, 660,000 degrees and 22,40,000 degrees—provided that the gas consusts of hydrogen atoms. There is good reason to believe that these "models" represent, in a general way, the internal structure of many (perhaps not all) of the stars.

But, on the rudimentary theory, this temperature should be proportional to the atomic weight of the material. If it was iron, the value would be 56 times Our calculations of temperature, then, depend far more upon what we suppose the Sun to be made of, than upon what pattern of internal density we assume.

Until about 15 years ago, no one would have dared to take this calculation very seriously. It seemed more likely that the atoms would be jammed together so tightly, by a much smaller pressure, that no increase could squeeze them into a much smaller space. If the atoms were rigid bodies, this might be nearly true, but as their properties became better known, it was realized that their outer layers of electrons would be shelled off and left to wander freely, leaving cores so small that the whole affair could be condensed to a very small volume. The only way to escape this, inside the Sun, is to have the particles moving about so fast that their collisions keep them from being jammed closer-and this is only a way of saving, in other language, that the material as a whole behaves like a very hot gas. So the simple calculations are good after all.

How hot the gas must be, to stand the pre-sun with the given density, depends on how many moving particles there are in it—since each, on the average, will have the same energy of motion. If they were all atoms of iron, which weigh 56 times as much as hydrogen atoms, the temperature would come out 56 times as high. But an iron atom has 26 electronsouts die is nucleus, and if these are all knocked off, the energy will be divided among 27 particles and the average amount, and hence the temperature of the gas, will be correspondingly lower.

This is a very fortunate thing for our calculations, for no matter with what sort of atom we start, the average weight of the pieces will be nearly the same. For sodium, for example (weight 23, 11 electrons) it is 1.92; for oxygen (weight 16, eight electrons) it is 1.78.

The calculated temperature inside the Sun therefore depends very luttle upon the chemical composition—with two important exceptions. A helium atom (weight 4, with two electrons) gives an average weight of 1.33 per piece, and a hydrogen atom, breaking into two parts, a weight of only 0.5.

For a star of the Sun's size and mass, built on Eddington's model, and composed entirely of hydrogen, the central temperature would (in round numbers) be 10,000,000 degrees, if it was all hehum, 26,000,000 degrees, and, if all of heavy atoms, about 40,000,000 degrees. Chandrasekhar's model makes the temperature 15 percent higher—a small difference compared with the effect of the atomic composition.

When we compare one star with another, we find that, for those built on the same model and of the same stuff, the temperatures at the centers (or any corresponding points) should be proportional to the mass divided by the radius For Sirius, for example, the mass is 24 times the Sun's, and the radius 1.8 times. so that the central temperature should be about 30 percent higher than for the Sun. The most massive star for which we have accurate data is 29 Canis Majoris an eclipsing system, in which the larger star has 46 times the Sun's mass, and 20 times its radius; its internal temperature should be therefore a little more than twice the Sun's. At the other end of the list of well determined systems is the faint companion of Castor-also an colpsing pair, composed of two stars having 63 and 57 percent of the Sun's mass, and 66 and 60 percent of its diameter The central temperature for both comes out 95 percent of the Sun's

These stars all belong to the great main sequence which runs from faint, small, red stars of small mass to brilhant, large, massive white stars For these, except for the biggest and hottest, the internal temperature should be much the same as for the Sun (which belongs to this sequence). Some stars, however, are quite different. For Capella, with 4.2 times the Sun's mass and 16 times its diameter, the internal temperature-other things being equal-should be a quarter of the Sun's, and for the great red giant Zeta Aurigae (mass 15. radius about 200) it should be only 7 percent of the solar value. Even this, however, is more than a million degrees (unless we assume that the star is made up almost entirely of hydrogen).

To get a closer estimate of the international temperature of a star, we must in some way be able to find out how much hydrogen and helium there is inside it. This looks like an impossible task; but there is a way to attempt it.

The rate of leakage—or flow—of heat of from the hot interior of a star to the surface must evidently be just equal to the rate at which heat escapes from this surface into space. We know this for a great of many stars. Allowance must be made for the the heat which escapes in the form of the invisible infrared or ultraviolet radiation, but this is easy except for the hottest and the coolest stars.

Now the rate at which heat will flow through the stellar gas—for a temperature gradient of so many degrees per mile—can be calculated. Under ordinary stellar conditions, this heat is almost entirely carried by radiation—sent out from one atom, caught by another, relayed again to a third, sometimes outward, sometimes inward, but working gradually toward the surface. We know enough about the properties of atoms now to permit a rather accurate calculation of the net rate at which heat will flow (if we know the temperature, pressure, and composition of the gas). Applying these principles to the stars (as was first done by Eddington, years ago) it is found that the net rate of supply of heat from the interior to the surface depends mainly on a star's mass--increasing very rapidly with this-but surprisingly little on its radius or its internal density-model. This explanation of the observed relation between mass and luminosity was the first great triumph of the theory of stellar constitution.

But the same theory indicates that the star's luminosity should be greatly influenced by the composition of its interior. If this consists entirely of heavy elements, the central temperature will be high, and the temperature gradient to the surface steep This greatly increases the heatflow, so that such a star will be bright. The more hydrogen there is in the mix ture, the lower will be the internal temperature and gradient. At the same time, the opacity of the gas-the resistance it offers to the heat-flow--will be less, but the first effect is the greater, and the calculated brightness diminishes. It is thus possible to calculate, from our knowledge of the properties of atoms alone, just how much heat a star of a given size and mass should radiate given the "model" on which it is built, and the percentage of hydrogen in it. When these calculations are performed for the Sun (using Eddington's "standard" model of density distribution) it is found that a star with no hydrogen comes out much too bright, one with a great deal is much too faint; while one with 36 percent of hydrogen, by weight-and the rest heavy atoms-matches the Sun exactly On this basis the mean weight per particle is 0.98, and the central temperature close to 20,000,000 degrees.

The calculated brightness, and the deduced hydrogen percentage, like the central temperature, are not much changed by reasonable alterations in the assumed density-model

If helium is present as well as hydrogen, other solutions are possible. For example, Strümgren (to whom these calculations are due) finds a solution for the Sun with 60 percent hydrogen, 36 percent helium, and 4 percent heavy atoms. This makes the mean weight of a particle 0.67, and the central temperature 13.000.000 degrees. This series of possible solutions ends with one containing 99.8 percent hydrogen, and with a central temperature of 10.000.000 degrees. Strümgeren finds, by this method, very nearly the same composition for most of the stars for which there are re-

liable data. For example, Strius (the bright component of the binary) comes out with 36 percent of hydrogen, Capella with 29 percent, if there is no helium present, and the other solutions are also similar. A few stars show evidence of different composition. For example, Zeta Herculis, which is four times as bright as the Sun, though of almost the same mass and surface temperature, gives only 11 percent of hydrogen; and sown of the lost stars at the top of the main sequence come out with 50 percent or more.

It is not surprising to find that most of the stars are similar in composition, for it seems reasonable—though we cannot prove it—to assume that they were somehow formed out of the same material.

The atmospheres of the stars, which we can study directly with the spectroscope, are actually very similar in composition, barring the effects of different temperatures in "stirring up" the atoms. In a few stars there appears to be an excess of silicon, or strontium, or barium. There is far more hydrogen than in the interior. Rosseland has explained this. The free electrons, which are very hight, tend to rise to great heights. To prevent this, there must be a small electric field pulling them down and the charged atoms up The electric force will have more effect on the light hydrogen ions than on heavier ones, and so will draw hydrogen toward the surface

BUT the greatest question of all restars shining. At the end of the last century we thought we knew Helmholtz and Kelvin, a generation earlier, had shown that, if the Sun, or any other star, contracted slowly, its gravitational energy would be gradually converted into heat Half this heat, and in some circumstances more, would be required to raise the temperature of the interior (which is increased by the contraction) but the rest would be available to supply the loss by leakage to the surface, and radiation into space. The star would automatically adjust its rate of shrinkage to the right amount to meet the annual radiation, and so keep shining for a long time. Applied to the Sun, this theory accounted for about 15,000,000 years shining, at the present rate, before it got to its present size. In those days, that seemed an impressively long time. But there is now conclusive radioactive evidence that geological time has involved fully a hundred times as long as this, and that the Sun has been warming the Earth very much as at present all this while. Whence has this enormous source of energy been derived?

For the first time, a reasonably complete and satisfactory answer has been given to this question: but we must wait till next month for space to describe this.—Princeton University Observatory, March 4, 1939.

More Water for Niagara

NIAGARA FALLS can be safe guarded of against serious self imparation in a spectacle. How this can be done has recently here shown by work carried out in the upper rapids of the inver. This should be welcome towers to the many millions of people that consider the falls to the greatest of our natural wond its. Once more the engineer has won his battle despite great of the expert get at the wond his battle despite great of the safe people of the safe people great of the safe people great of the safe great of the s

Every now and then large masses of tock detach themselves from the crest lines of the two falls, and immediately there is excited clamor that one or the other of the two cascades is

'committing suicide." If such were, indeed, the fact, then the falls have been busy at their own destruction ever since they started upon their stupendous recession some 35,000 years ago at the orig mal escarpment seven miles downstream from the present site What is the puny significance of a few thousand tons of detached rock com pared with the inconcervably great volume of rock that the river has carved out of the varied formations in the period mentioned while eroding a gorge mile- long, from 200 to 300 feet deep, and of varying but extensive width? Each mass of rock so released is merely a recurrent reminder of the fiveless forces that have been at work during past millenia and will continue for ages to come

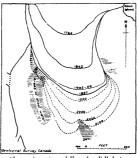

The earliest record of the contour of the Canadian or Horsesboe Fall, which has been altered by crosson in latter decades more than the American Fall, dates from 1764, and at subsequent intervals the crest line has been observed and registered by drawings. These records disclose that the Horsesboe Fall has undergone considerable change of crest line in the course of the last 200 or 300 vars, but none is, relatively peaking, sarrely more than an inconsequent mibble compared with the moditations that have taken place in the

The Ningara River, in its approach to the two cascades, flows over a thick stratum of rock which is a hard limestone formation and lighly resistant to eriosive action. The river level drops about 50 feet to the mile as at descends to the falls, and because of the swiftly

By R. G. SKERRETT

moving water, the lip of the Horseshot Fall is ceaselessly exposed to erosive action. As a consequence, the recession of the crest line, due to this wear, had been found to be as much as 4.2 feet in a sin-

Changes in contour of Horseshoe Fall during the years from 1764, and predicted changes

gle year; and between 1842 and 1927, the mean annual ate of recession is known to have been 3.7 feet. Since 1905, however, the mean recession has been 2.3 feet The lessening of the retrogated movement is largely the result of a reduction in the volume of water pouring over the falls, due partly to the diversion of water for power

Even though natural forces are mevitably bound to coninue their crosive work at both the American Fall and the Canadian Fall, and recession will persist until Niagara Falls opens the flood gates of Lake Erie thousands and thousands of years hence,

purposes at points upstream

it is still practicable, as has been proved lately, to direct the flow of the water at the falls in such a manner as to modify its crossic action. It is also possible to large about a better balanced distribution of the water throughout the cuties seep of the creal line of each fall. Improvement in the entire spectacle may very be achieved with a lesser volume of water than ordinarily passes over the falls.

These betterments were inducted ascashle in a report made about eight sears ago by a joint international board composed of emment. Americans and Canadians. The board disclosed that competent eigeneess were satisfied that errosion could be reduced and the picture-queness of the falls enhanced by controlling the flow of the water to the cast ades through the medium of submerged wors, but nothing to that end was done at the time by either interested nation. Something now has been done, and the Horseshoe Fall has gained in beauty in consequence.

The international report to which reference has been made stated that more water could be diverted for power purposes yet still leave an ample volume to maintain the falls in their prime as a

Vertical section of the falls showing the various strata, All slope downward to left, upstream

speciale). This is a matter of importance because the Nagara River has been one a source of indispensable electric energy for nearby communities and essential midistrial activities. It is a fact, however, that a condition of lowered water in the river, mainly due to nature is fickleness, has brought about the building of a submired went that incidentally has been fitted the Horses-how Fall. Primarily, the went has been constructed to restore to one of the Canadian power plants the volume of water that it had at its disposal when first put in operation 35 votats are:

During the succeeding three and a half deeduck, the level of the tree dropped because of much diminished randall, over a producted period throughout the expansive watershed of the Great Takes Also, the Chicago Dannage Canal, the improved Welland Gand, and the New York State Barg Canal have made increased darks on the waters of those lakes, Furthermore, expanding power plants, with their intakes

above the falls, have withdrawn more water from the river to meet the demand for larger blocks of electric encigy. To satisfy their customers, power companies have successively amplified the capacities of their station- In 1904, the total installed capacity at the Niagara Falls stations was but 122 750 horsepower Today. it is 1563,700 horsepower The lowering of the river level became particularly serious for the Canadian Niagara Power Company, Ltd. To re establish the water level in the forebay of its plant, located about a third of a mile above the Horseshoe Fall, that company, with the full approval of the authori-

ties, récently has built a subappeouwen about 930 feet long that extendfrom the Canadian shore obliquely upstream. It reaches out against the sweep of the river like the forearm of a swimmer, with a curved elbow where the structure is tied to the shore at the down stream side of the forebay entrance.

The weirs proposed fen years ago were to be rockfill structures. The went that now serves the plant of the Canadan Nugara Power Company, Ltd., is of concrete of a superior character. The structure is designed to be permanent and capable of meeting the most riporous conditions. Its construction called for unusual precautions and engineering expedients. The work necessitated the construction of a temporary operating pier of the same length as the concrete were; and along the downstream side of the pier was successively formed a cofferdam of sufficient length to norm tile ferdam of sufficient length to norm the

Above. Temporary construction pier that was the base of operations. Below: One of the cells being made ready to be swing outboard and lowered into position

ment.

pouring of the weir in a 72-foot section each time—the cofferdam being unwatered so that the concrete could be placed in the dry and handled in a manner that would make certain of highgrade workmanship throughout.

Although the original design of the weir was planned broadly to meet conditions under water as they were largely assumed to be, nevertheless provision had to be made for modifications as more exact knowledge of the river was obtained during the building of the temporary pier. That pier, besides affording a working platform and creating an area of relatively quiet water along its downstream side, was also to serve experimentally as a weir and, by means of various tests, to disclose just how high and how long the permanent weir would have to be to raise the water in the forehay of the power plant to the level that had existed when that station began opcrating and withdrawing water in 1904 It was essential that the weir should not be visible or detract from the natural beauty of the rapids above the fall. No exact soundings had been made pro viously along the line chosen for the weir The swiftly running river and the nearness of the fall had made such work not alone too hazardous but too costly Therefore, the construction of the pier was, in itself, both a venturesome and exploratory undertaking, and it was counted upon to reveal, as it advanced outward, the changing depth of water and the varying features of the rocky river bed. The procedure was more or less like wading into a treacherous stream with the prospect of a sudden and perhaps dangerous drop at any mo-

The pier was made up of numerous unit cells fashioned of structural steel and having the form of four legged rectangular frames, which were assembled on shore and set upon the river bed, one by one, as the mer was extended oblique ly outward from the shore. Each of the four legs was a heavy I beam, and the lower part of each leg was shortened. when necessary, to conform to the river bed To give the cells a better and a uniform footing, each leg had welded to it a sturdy cast-steel spiked shoe, added after any excess length of the corner legs was burned off. In the upper section of each cell there was a timber lined bin capable of holding 50 cubic yards of gravel ballast that was added each time after a cell was in its assigned place in the pier. To stabilize the pier further, each leg of each cell was anchored to the river bed by two two-inch steel dowels that were driven into holes drilled into the rock beneath each leg after the cell had been set. Before a cell was lowered

Within an unwatered length of cofferdam, beside sheltered flank of pier, while wooden forms were being creeted to pour a 72-foot length of submerged wer

into place, precise soundings were madewhere the four legs of the next cell to be lowered would rest and the bottom was cleared of all loose material to assure a footing on firm rock The soundings were made from a platform cantilevered out from the last cell in position. In this manner, the pier was kingthened cell by cell after deliberate and careful preparation; and in the end the pier was composed of 51 cells

EACH cell had a width of 12 feet and a length of 24 feet, and the cells were arranged with their length across the axis of the pier There was a gap of six feet between succeeding cells and there was a free space of 12 feet or so between the under side of each ballast bin and the bed of the river. The gaps between the cells and the spaces below the bins could be closed when or where desired by stop logs--rectangular timbers-dropped into place between the flanges of the upstream legs of the cells This provision made it possible to obstruct the flow of water through the pier structure and permit it to function as a weir of variable height. In this way, the engineers were able to ascertain how long and how high the permanent weir should be to raise the water in the forebay to the required level. The six foot gaps between the cells were designed to provide ready passages for floating ice so that the obstruction would not cause an ice jam that would be almost certain to shut down the power station, for the work had to go on throughout the winter.

On top of the cells of the pier were laid timber stringers, crossies, and the tails for two tracks—one for a large locomotive crane which helped to handle the cells and do other heavy work in connection with the actual construction of the weir and the erection of the paralleling cofferdam, and the second, a narrow-gage track over which were hauled carloads of concrete and other materials. The pier was extended until it was made up of 45 cells, after which stop logs were put in place and the pier was used as a weir experimentally for several weeks. After continuous observation, the engineers decided to lengthen the pier by six more cells; and when so completed and with stop logs installed, it was found that the river flowed over the makeshift weir at a level of five feet higher than on the downstream side of that barrier, To deflect to midstream the violently eddying water at the outer end of the pier, there was suspended there a cantilevered frame of steel and timber having a length of 48 feet. This served its purpose, and protected from any troublesome disturbance the area

in which the weir was to be built. The building of the weir started at the outer end of the pier and was gradually lengthened until its inner curved section met the shore. The cofferdam within which the weir was reared was formed of a series of steel frames around which water-tight walls were made up of interlocking steel sheet piling-the enclosed space then being unwatered by a group of pumps of large combined capacity. Each rectangular frame section had a length of 24 feet and a width of 25 feet, and the frames could be tied together or disconnected so as to be used repeatedly in pouring, length after length, of the concrete weir. For this purpose, four sections of cofferdam, 96 teet long, served successively for placing concrete in a unit 72-foot length of weir; and the shoreward fourth section, at the conclusion of one such operation, was left in place to form the outermost part of the next unwatered length of cofferdam within which would be poured the succeeding 72 feet of weir. Besidecleaning the river hed to expose sound to the four successive for the succeeding surface for the concrete, the weir was further anchored to the basic rock by means of two lines of h ax steel dowels driven into the rock and protecting above it.

Despite the hazardous conditions surrounding the entire 10b, the work was carried forward to completion with but a single unexpected setback, which occurred where the project crossed diagonally an eroded channel 12 feet deep and 60 feet wide that was filled with a tightly packed mass of gravel and boulders. This was not serious. When the work was finished approximately \$435,000 had been expended. The depth of water in which the weir was built varies from 12 to 22 feet. Work on the project was carried on for more than a year as the pier and the well were constructed and then the former was removed.

WITH the temporary pier and all sections of the cofferdam dismantled and removed, the only evidence of the subaqueous weir is a long line of tumbling water that is much like the other turbulent areas of the rapids where the river rushes downward over hidden reefs. Aside from restoring the original water level within the forebay of the power station, the weir causes the water near the shore end of the structure to continue onward to the Table Rock flank of the Horseshoe Fall and to provide a better distribution of the water at that point. It thus adds to the beauty of that cascade where the lowered river had exposed a considerable expanse of rock contiguous to the crest line.

The werr has demonstrated how other weirs may be constructed and be effective in so distributing the flow, especially at the Horseshoe Fall, as to reduce the rate of crossion greatly at certain sections of that catarect and make the water that does drop over its crestline the means of enhancing its effectiveness as an awe-inspiring spectacle. In short, Niggara Falls can, in a measure, be saved from self-defacement, thanks to the cunning of the modern engineer and to his associate, the well equipped and resourceful builder.

The Dr. Oscar Parkes, the noted naval authority, throus light on the puries of naval rearmament of the naval powers in two long articles that are coming soon, As usual, he made the dracings.—The Editor.

COMFORT COOLING

N aluminum-foil-coated operating room in Blodgett Memorial Hospi tal, Grand Rapids, Michigan, may hold the answer to science's long search for an ideal climate. In this unique room, air temperatures may be maintained as high as 90 degrees or above, with aver age humidity, without any perceptible discomfort to occupants. This amazing set of conditions has been made possible by an important development of Dr. Clarence A. Mills, professor of experimental medicine at the University of Cincinnati, and may bring about new economies in building insulation and cooling and heating through control of human comfort by radiant mean-

The Bidgett installation represents of the Bidgett installation represents of the properties of the pr

aging results.

The Mills system is a departure from the conventional types of heat control now in commercial and home use, which depend mainly upon transfer of heat by convection and conduction, in that it proSignificant New System . . . Proved by Hospital Tests . . . No Costly Equipment . . . Employs Body-Radiation Reflectors, Absorbers . . . Cools No Air

motes the control of body heat by radiation. As most persons know, radiation is the transfer of heat between bodies of dissimilar temperatures which are separated from each other by an appreciable distance. The heat rays proceed through it and travel with the speed of light. In a highly heated room, for example, a closed window, chilled by the outside an, will rapidly abort the heat radiationfrom a person's body standing close to at, with the resont will feel uncomfortably cold in spite of the high temperature of the surrounding air.

In the Blodgett operating room, the tadunt heat from persons in the room passes to the walls, which are covered with embosed alumnum foil. The alumnum foil is highly reflective to these heat rays and low in heat radiation and in absorption. These properties, comlined with the diffusing effect of the embosed pattern, cause the rays to be reflected at contiles singles, perhaps many times, so that the majority of the heat rays to do come into contact, somer or later, with two black wall-panels, approximately three feet who by 15 feet long, in which circulating fluid has lowered the temperature to 50 degrees or under. These panels absorb the heat rays as a blotter takes up ink.

One of the beneficial features of this method of lus-pital "comfort cooling" is the fact that the installation controls the room climate without changing the surrounding air, thus climinating undesired drafts during surgical operations.

THERE is no susation of thermal skin shock when entering the room from an unconditioned atmosphere. In spite of the high temperature of the foom and the fact that heavy appared such as heavy duck gown, rubber gloves, hat, and mask is worn during an operation, profuse perspiration of the occunants is eliminated.

Although the Bholgett installation is designed for comfort under high temperature conditions such as are necessity in operating rooms, tests have shown that, with slightly modified dissigns, the process can also be efficiently reversed. By heating instead of cooling the panels, heat may be radated back to the bodies of the occupants to make low tempo status; also feel comfortable

low tempt attires also feel comfortable. Attention was first called to the Mill-method of heat control at the meeting of the American College of Surgeons in Totonto in 1937 where it was brought out that D. Mills had made the novel approach to comfort cooling. As a reward of the meeting, Dr. John F. Gortell, Director of the Blodgett Memorial Hopping the property of the Blodgett Memorial Hopping the property of the surface o

Although Dr. Mills' development hamany proved possibilities, the inventor contends that there are several featurewhich will probably have to be improved before a desired degree of perfection isobtained. When this point is reached, the equipment will function efficiently for both home and commercial use, Dr. Mills believes.

In a comparison of costs between the new theory and present-day au-conditioning systems, Dr. Mills and impartial engineers have computed the operating expense at from one third to one fifth that of air-conditioning equipment of similar capacities.

Temperatures of 90 degrees and above are comfortable because the body's heat, radiated to the aluminum walls, is reflected to the cool heat-absorber (black)

Protograph courter U 8 Forest States

Portable tie mill cuts 300 ties daily, the product of four men. Such mills can be set up at the timber source, eliminating long hauls

Some trucks carry their trailers into the forest where, hooked together,

In some cases lumber floats down man-made rivers or flumes to a loading point on a railroad or a river Below. A tower skidder does not require a tree at the tracks; a steel spar is mounted on the machine

fighting pump. Two overhead steel tubes protect the driver against branches

"TANDING sturdier than the proverbial oak, the head of a tall steel spar reas above a Washington logging camp; across canyons, strong cables skid to the side of the spar heavy logs which vesterday were 200-year-old trees. In a nearby Oregon forest a portable tie mill salvages second-growth timber, Douglas firs too small for the big outfits to fell.

These two timber-handlers represent the change in forest machinery which is witnessing the disappearance of big, costly mills and the evolution of power units with which small operators pene-trate the forests, logging small areas which formerly were not touched.

Nick Meyer, for example, operates a four-man tie mill near Lapine, Oregon, cutting 300 railroad ties daily, the product of a faller, sawyer, offbearer, and stacker. He moves through second growth timber, some of which is less than a halfcentury old, cleaning up odd corners passed by former logging outfits.

Elsewhere through the northwest, other novel machines speed the cutting of merchantable timber Saws, powered by electricity which turns endless chains, bite through the wood, felling trees in jig time. Diesel engines in mul tiple units, gasoline motors, and steam ringines bring the big timbers to rail and water. Lumber, rough cut at mills deep in the woods, floats down man-made rivers to shipping points. From the moment a lumber ack shouts, "Tim-b-u-r-r! Timber down the hill," to warn all within hearing that a tree is falling, fast, mobile machines take up the job of rushing it to distant markels.

Standing on a railroad car bearing a steam-engine and winches into a Weyerhauser forest, the steel spar and skidder may be moved all along the line. pulling logs through the air from cutting areas a half-mile distant. The skidder system is the method commonly used for gathering in logs on large cuttings.

IN THE $\overline{ ext{Woods}}$

It involves use of a skyline, or two inch cable suspended between two supports. Along the skyline rides a steel carriage weighing nearly as much as a small automobile, to which are attached hooks for picking up one end of the logs. Back and forth moves the carriage, skilding logs to the landing

F IVE years ago most timber reached the chipping points on radiously, built by loggers deep into the forests. Loggers recently have patterned their operations after the construction industry. Now, logs by tens of thousands are lifted by cables and towed through mud and snow on tractortype trailers, or ride over solid truck tires and truck differential housings to forest roads cut by shape-edged buildozers. Only recently there appeared on Oregon two such machines built by the U. S. Forest Service, one a baby scarcely three feet wide, the other a sonting gainst capable of building several

miles of six-foot road between breakfast and dinner. By swinging two levers, the operator can convert this machine into either a water pump or an oil pump, for fighting fires or setting backfires when a logging camp is threatened.

Unable to turn around on the narrow roads, trucks carry eight-wheel trailers on their backs to the loading points. There other machines pick up the trailers and set them down in the roadway. After the units are booked together, heavy loads of logs are piled on for the rough journey out of the forest. Few of these are one-purpose machines. Diesel shovels may be excavating for a road today, loading logs tomorrow. Locomotive cranes, powered by steam, lift logs or right cars over-turned in a wreck. Hundred ton locomotives are passing, for each piece of today's forest machinery must be capable of handling several jobs to keep up the accelerating pace of logging - Indrew R. Boone.

MONTHLY DIGEST

STOPPING THE

PROTECTION against the ravages of the marine borers on wharf pring in all but tropical waters is now offered by a unique type of shield with an estimated life of at least 15 years. Cost of mistalling the shield

Applying a small section of wood on shield to stop marine boreis

varies according to territory, but in no case does it exceed 50 percent of the replacement cost of the piling, according to its producers and INCO magazine

Since almost all marine borers attack wharf pling between the mid-line and the low-water mark, the sheld is designed to cover this section only Length can be varied in accordance with the demands of local conditions.

Essentially, the shield consists of a wooden casing treated to absolute refusal with recostic. After being applied, the casing is then filled with sand A patented device at the base of the shield prevents the escape of sand after in-stallation and aids in centering the shield around the pile.

The base is made up of 12 staves approximately 15 inches long, fastened in two semi-circular sections hinged together. This base is applied around the pile above the water line and the two semi-circular sections are bound together with a Monel wire hoop and Monel cip assembly. The base is then forced down as other sections of staves are added.

The section staves, each provided with internal and external members to engage the top of the corresponding stave below, vary Conducted by F. D. McHUGH

AERO-THREAD SCREW

THREAD

MAKING use of a new system of application, the "Acro This off" series where all system is meeting with wide interest from manufacturers and industrial concerns, particularly for those applications where the maximum reliability in series fastenings is required.

required seten was developed promainly for in the arrestit industry where high strength study, and cap series, are required that particular advantages for series that fasten into tapped holes in light alloys such fasten into tapped holes in light alloys such as those of aluminum or magnissium. Because of the especially high strength that can be obtained from an Arch Thread series or study, this series vicem is attractive or study, this series vicem is attractive and the properties are desirable.

The outstanding feature of the Arralativad series system is the use of a spirally wound insert or bushing of precision formed, high results, bornes spirag were. This meert its into the tapped hole by screwing into the threads and the design of the meer is such that, while it can readily be screwed into place, when once it is installed it becomes a fixed part of the tapped hole. When the stud or cap series is sessabled, its bearing is, therefore, against and in direct contact with the hard spiral bronze insert—instead of

The three-ton, \$2 inch Prex; telescope mirror for the McDonald Observatory, escool largest in the world and the most accurate mirror ever tested, was vrapped in Cellophane for shipment from the Warner & Swasey Co., in Cleveland, to Mt. Locke, in western Traxs, Cellophane was chosen because it is non-porous, and would not collect mosture during the trp. If oil or wax paper were used, there would be danger of getting spots on the mirror, which would have to be polished off. Even if the Cellophane touches the polished surface of the mirror, there is no possibility of aparting The covering also keeps out all dost

against the soften metal of the light alloy part. The thread on the Aero-Thread stude and cap serves is of a shallow rounded form, the soften are served in the soften are soften of the meet. The complete chimination of all sharp corners in the thread on the stude or cap serves allows the use of stude and servess heat-treaded to high values of ten sile strength, and these servess have very much greater shock resistance and fatigue capacity than is possible with servess having a server of the student serves the student server of the server of t

Threads.

The new system simplifies the servicing of stude and screws, It protects the threads in the female parts from wear and damage and thereby eliminates the need for oversized screws and stude, or for re-tapping the holes when replacements are necessary. When an Acto-Thread studior cap screw is removed from the tapped hole; it is generally

found that it can be replaced with one of the same size and still maintain the original designed thread fit. If the insert should become damaged or worn, it can readily be replaced with a new insert and the threaded hole will be brought back to its original dimensions.

The ArroThread system also allows—for the first time—the untestrated use of cap screws and removable screw fastenings in the light alloys of aluminum or magnessum, as the insert fully protects the soft threads in the tapped hole and its anti-frictional property allows—smooth, non-wearing, and monsering engagement for the cap screw

FROST IN THE BAKERY

Q UCK freezing is expected to help bakers solve their most vexing problem, that of too quick staling of bread Recent investigations have shown that bread can be kept fresh if it is frozen and stored at low temperature as soon as it is baked. Experts were

LZ 130 during a test flight. Below. A view down one of the cat-walks, showing typical construction of the air-ship, and the auxiliary rudder-control station

unable to distinguish any difference between freshly baked loaves and others that had been stored for as long as 20 days at 31 degrees. Falmenhett Even after nearly from months hra day part at the low temperature was quite salable Possibly bakers may now add low temperature cold stores to their plants to help take up slack between production and demand

Within recent years, important progres has been made by back is toward a baf which keeps better and methods of wrapping and keeping bread fresh longer. However, non- of these has prouded for so long or so satisfactory keeping as quick friezing. The importance acl is lower than any met commercially except in modern quick freezing practice $\sim D/H/K$

DIVES

THEORETICALLA. engineers say, there is no limit to the maximum diving speed of planes under test, and they believe the record of 670 miles an hour, set by Leutenaut Troy Keith, of the An Coips, may be surpassed. Pulling out of a dive is the difficult thing for the plot, for he can withstand a strain of Hg for only about a fifth of a second

To Follow the "Hindenburg"

NDETERRED by the terrible disaster of the Hindenburg, the German Luftschiffban Zeppelin has completed and suc cessfully tested the LL 130, which is the 119th large rigid airship built by this com pany (eleven others were designed but never built). Basically, the design is very similar to that of the Hindenburg, although many refinements have been incorporated The length of the new airship is 803 feet. and its maximum diameter is 135 feet, giving a fineness ratio of 6 to 1. The lifting gas capacity exceeds 7,000,000 cubic feet. The 16 gas cells were to be filled with beliam, but the controversy with Secretary Ickes makes it rather doubtful that the German company will be able to obtain this valuable non in flammable gas from the United States

The passengers in the LZ 110 will be

housed within the hull in 20 cabins luxurous enough to stand conjugarson with the accommodation offerd on modern occan lines. In the construction of the furniture, duralumin has largely here insel in place of wood, as a further weight saving measure, holes are punched into the metal ribs and braces of the furniture.

Compared with the archip the ariphare is childlike in its simplicity. The structure of an airchip is an engineering problem of enormous complexity. The structure of the LZ 1/0 is of the classical type with 36 longitudinal girders and wire-braced frames at intervals to house the gas cells and reinforce the longitudinals.

Some curious statistics are supplied to us by the Luftschiffbau Zeppelin length of frame girders is about 14 miles, the number of rivets used is 5,500,000, the total length of steel wire used is about 80 miles, and the area of cotton material for the outer cover is about 33,000 square yards. Four Damler-Benz water-cooled Diesel engines, of 800 to 1000 horsepower each, supply the power The Diesel, with its great reliability, is the logical power plant for the airship where weight of engines is not quite of the same consequence as in the airplane One of our photographs shows the LZ 130 in flight. Another photograph illustrates typical con struction, showing the interior of the keel and the auxiliary rudder-control station.

It is sometimes believed that all airship work in the United States has ceased and that Germany alone is active in this field. A symposium on airships held at the Annual Meeting of the Institute of Aeronautical Sci-

ences belies this pessimistic view. Thus, the Navy has recently received a 400,000 cubicfoot non-rigid air-hip or "blimp." In the field of large airships, Congress has authorized the construction of a rigid airship of only 1,000,000 cubic feet to be used for training and research purposes Dr. W F. Durand, Chairman of the Special Committee on Air ships, speaking at the above mentioned sym posium, pointed out that since the great disasters to the Akron and the Macon, an immense amount of structural, aerodynamic. and wind tunnel research has been carried out, which has filled up many gaps in our knowledge Dr. Durand expressed his viewas follows. "In our opinion, we are now in a position to design and construct airshipwith an assured margin of safety abundantly adequate to justify continued construction and operation '-- 4 A

FLIGHT BY WOMAN POWER

WELL known engineer of Philadel h phia, Enea Bossi, has built the 'Acrowhich has been flown for three gum ters of a mile with all the power supplied to the propeller of the very light monoplane by the legs of a muscular man. The actual exploit took place in Milan, Italy In Cormany studies in man namer field in bring undertaken in all seriousness. In Italy the government has offered valuable prizes for flight by human muscles. Buchard C. du. Pont is reported to have said that given a glider with a foot-driven propeller, to be used occasionally, he could keep aloft indefinitely and fly across country at will, Evidently the question of muscular flight is not a fantastic one, and is being entertained in many is sponsible quarters

Dr. W. F. Gerhardt, of Wayne University is attacking the same problem in a totally different manner. He has built a "grocycle which is no radius a bright and problem in the brook of the same plest possible form. Its bifung element is a two-bladed, variable pitch propoller of 14 feet domineter. The air-serve is mounted on a vertical shaft driven through a 2 to 1 pinnon grar by ordinary huyele foot pedals. As set up in the Davie's laboratory the grocycle is not yet a free-flying which, but is controlled faterally by a stationary tripod. The

One woman-power

charming Mrs. De Tuscan shown in our photograph has created three records with this unique device: the first vertical "flight" by muscular power, the first "flight" by muscular power ever achieved by a woman, and an ascent or jump-off of one eighth of an meh. At any rate, this is a beginning

An interesting piece of research would be to determine whether a light plane with concentional lig driven propeller, a flapping-wing machine, or a species of helicopter would be best adapted for musualar flight -4 K.

MODERN COCKPITS

THI Boring Copper built for Pan Amertican has passed its manufacturer's testsible Burg colors. We propose here to focus attention on our siginfinint feature, the control tous

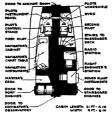

In the early dave of flying the plot's excitant was this more than a calibbable. Even a large mad-passinger plane of 1927, such as the Boreng 49.4, but a cockput volume of only 37 cubic feet. The new Chipersontial from has a volume of 1028 cubic feet, more than twice the volume of the current passinger to comparison of the Borong 277 D is win eigened Jand transport. Much common is needed to give the cive complete me to know a multiplicity of equipment, Both comfort and equipment are essemital to safe-conduct and equipment are essemital to safe-

The control room is, of course, located on the upper deck of the hull, with ready access to the engines through doors on each side of the room. There are six posts of duty in the room. The first and second pilots' stations are at the forward end, with a door to the anchor room at the very front end of the cabin. In front of these stations are the sim plifted instrument panel, the gyro pilot, and the windshield. There are four other posts of duty. A real advance in control room design and practice has been made, which relieves the pilots of the almost intolerable complexity of duties they have to undertake in smaller ships. If the instrument panel ahead of the first pilot has been so simplified. it is because duties have been subdivided among five or six men and the pilot's duty inow merely to control the flight in a given di rection at the altitude and speed prescribed by the navigator. The navigator has plenty of

The spacious control room of the latest Pan American Chipper ship and, below, the arrangement of the flight deck. See also illustration on page 278, this issue

CONTROL CABIN

iron for his calinet, chart table, and may gatumal instruments. The radio aperator, placed to the right, maintains contact with the ground stations and furmalise, radio hearings to the navigator. The flight regimeer has at his disposal the complete set of power-plant instruments and se close to the doors leading to the engines. The master or watch officet curvalates the functions of the other even members, assuming the functions of a capiam. At the back of the control town is the door to the avagator's observatory. Fur

nishings are simple, anobirusive, highly comfortable

For relief members of the crew off dury there are sleeping quarters located in an afticompartment of the upper deck. It is remarkable how these large flying boats approach the character of the large surface vissel.

MILITARY AIRPLANE SECRECY

HIGH RANNO. Any officers have poured on the officers have poured on two difficult us to man-tain servery in regard to new arrplane design. Once a machine has been flown, it cannot scape observation and the telephoton for scan be brought into plan by the possibly bustile onlooker. Finally, when an accedent purpose, the form pages of the dauly pressumeduately communicate a wealth of information for the benefit of foreign countries and there is nothing in a democratic country to prevent the most valuable information being made available to skilled European interpreters.

Take for example, the accident of the Anny's "fasts plane" as reported so admirably in our newspapers, with photography to make the situation clearer, I will be remembered that Leitenant Benjamin S. Kel-eye (rashed the plane after a highly successful transcontinental trip from March Field, California, to the club Stream golf course must east of Mitchell Field on Long Island. We have not the slightest bestation in discussing the machine here, even though we agrees in Europe will sentime the newstories with even greater care and will learn even more than the writer of these lines.

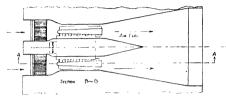

even more than low writer of those lines. The speed is given as 500 miles an houst make it is the state of the state of the state of the notice is thereby served that only speeds of over 460 miles an hour will give a nation speed supremacy. The engines are streamined into the wings on each side, and there is no inkling of an air cooled cowling. The interence is that high-powered injunct-cooled. Allison engines, of twelv-explander design, are now available for arriphane construction,

Yankee Clipper during a test run

Sketches above and below show details of the novel English scheme for cooling water-jacketed arplane engines without introducing undesirable air resistance

Because there is no way of getting higher speed with a single engine, and because control, laterally, with a single powerful engine is very difficult.

The new stories speak of two hours to carry the tail similares. The inference is that aerodynamic diagres saved thereby it is evidently better to build a tiny cockpit just logenough to house the jubble and use booms or outriggers, than to construct a constitutional diseduge to support the rear control surfaces.

We read of the use of a trevel bunding gear. That means that even for the Jastest multiray machine, the trevels landing gear has come into its own. The calon is supercharged for stratespher to substratespher work. In the strainhead mess of the took which can be closed by set clades fluid with which can be closed by set clades fluid with the surface. The new machine can outly the "brigg forties" bendies: Spain it can be "brigged forties bendies and it is disapped to be a most formalish can use of the bundler.

So the accident served to give the foreign students of the art a mine of valuable information

The muchine was built by Lackband Aneraft in 18 months of hard work, and the eccident in no way invalidates the skill of the designers. These extremely fast slupeven if they carry the latest instruments and flaps and other devices, still require giral skill, and still encounter accidents even in the hands of such fine veterans as Lieutenant Kelsey In fact, the question arises wheth i the new 1P-18 is so advanced, so clever, that the practical mark of military design has been overshot. Here is a ship which must cost, even in production, something not far from \$100,000, Here is a ship which evidently requires great care in flying. Here is an allmetal ship, beautifully streamlined and finished, which it is not casy to repair or maintain. Here is a case of putting a great many eggs in one basket Would it be in time of war feasible to build and operate a sufficient number of such machines? Would it not be wiser to have a greater number of airplanes, simpler in design, not quite so fast, but built at less expense and easier to oper-ate? Where will we find the super-men that

the world's fastest planes require for han

We hope and presume that those responsible for our military aircraft equipment do not overlook these conselectations. We do not want an air force of theoretically perfect aircraft, but in musificient numbers to put up a real fight --A K.

ENGINE RADIATORS WITHOUT RESISTANCE

A FEW months ago we mentioned briefby, and on the basis of incomplete reports, that two young English engineers.
Charles John Stewart and Frederick Willam Mereduli, had desired a radiator in
which are resistance was found to be nil or
even negative. Now a study of the patient
(nables us to give a more complete state
ment of the principles of this device.

Let the reader glance for a moment at the diagrammatic sketches. The engine, with its two rows of evhinders in V-arrangement, is placed within the greatest depth of the airplane wing. On each side of the engine, air tunnels are provided with openings just behind the leading edge.

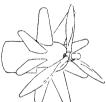

When flying at high speed, the air enters the opening of the tunnel and some of its kinetic energy is converted into pressure, so that cooling are side driven through tubular radiators placed near the entrance to the tunnel. Passing through the radiators, the air maturally loses pressure. But thereafte the air passes by the exhaust annifolds of the engine, captures heat and recovers pressure. Later, the cooling are muse with the exhaust gas from the manifolds and again the pressure is rated or all less timationed. The two tunnels converge and pass into a narrow hurrountal outfor at the trare edge of the wing, where the air leaves with great velocity.

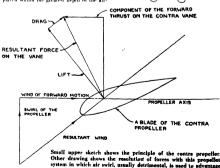

The reaction of this are jet, produces a forward threas which more than compensates for the loss in pressure when passing through the radiators. In effect, a speris of auxiliary gas engine has been provided whereby some of the heat of the cylinders and of the exhabits has been put to work. We consider this to be a remarkably ingenious idea which deserves to be carefully tried out in distance $\mathcal{L}(K)$.

EXPERIMENTS WITH THE

CONTRA PROPELLER

Till amplane propeller accelerates the air in a backward direction, that is how thrust is obtained. But it also imparts a ro-

tational motion or swirl to the air stream, and this swirl is thoroughly undesirable for two creaons. Since the swirl means kinetic energy in the air stream, rotation of the air movives some loss in efficiency. Also, when the swirl of the propeller strikes the vertical air surfaces, it produces a turning tendency for the whole sirplane.

Three defects have long been known, and a device to eliminate the swirl, called the contra propeller, has also been known for a long time. It is only quite recently, however, that definite figures on the contra propeller have become available through experiments at Stanford University, reported in a Technical Note of the National Advisory Committee for Actionative.

the of our drawings above the punciple of the conta propeller, in which fixed vanisher drawing mixture how the work is also mixture bow the ward is taken advantage of to produce an element of forward threat The forward motion wind and the swill combine to give a resolution would which makes an imple with the axis of the propeller. The life is always a right to design of the produces a forward combinent of this skiller as a resolution of the produces a forward combinent of this skiller.

Experiments in the wind tunnel indicate that for relatively slow fixing peoels, the contra propeller might increase the efficiency some 2½ percent, and climinate half the surf But at high speed, efficiency was annually lost by introduction of the device these results are less satisfactory than had required to the complete of the contract of the con

AIRPORT WEATHERMAN

T is convenient for men at work inside a control room at an airport to be able to determine instantly what the weather is doing outside. Hence the development of the bullen P. Frac Airport Weatheram Outside there are located a wind vane, a three cup anemometer, and a themometer The wind direction wane operates a synchronous previator in a bousing located mimediately

The airport weatherman and, below, the indicating punel used with it

A light plane for the private flier

below it. The inverseout of the generator is communicated electrically to a companion motor in the control room, which actuates the data of the wind direction indicator. The automoter also operates an electric genrator which works with a companion motor letow. The distance reading thermometer is copusped in existomizy fachine with egiplicity patcher is the man who uses the Aupent Watherman most, but it is of qual importance to others working on the airlines— 4. A

An Interesting

POR several years, Frederick F Week, Chef Engineer of the Engineering & Research (orporation, has been engaged in the problem of holding a high plane which would be entirely suitable for the private owner and fler. The Model 310, illustrated in the photograph, was designed by Mr in the photograph, was designed by Mr Accounter Authority, and offers many increasing features for the greater fler.

Thus, the 310 is almost entirely of aliminim alloy construction—which is as it should be. The only concession, apparently, is that the outer wing panels as a fabriccovered. A four-cylinder, investred, air cooled engine of 55 horsepower is proved. This is just about the right power, and the vision alread is very good, as our photograph indicates. There is aid-by-side seating, with a sliding transparent enclosure. Again we agree that light planes should provide an approximation of the production of the processing of the processing

We are also informed that, in a few mintres, ruider and ailerone can be inked up. We do not believe in the two-control arttives, ruider and incention the two-control artplane—that is, one in whech the ruider has a plane—that is, one in which the ruider has disappeared—but the co-ordination of ruidder and ailerons may be useful at times and the idea has some possibilities. Also, there are as so much longitudinal stability provided and so much vertical fin area below the associated in the size of the size of the size of the stall the airplane or to keep it in a spinve highly destrable characteristics. With a gross weight of 100 pounds, a top speed of 0 100 miles are hour, a sean of 30 feet. and a wing area of 140 square feet, the new design looks very near and has aroused considerable expectation in the aviation world -4 K

"PREGWOOD"

THIE Formera Insolution Company has amounted a new product, Pregwood, made by vulcanizing together thin hammations of wood impregnated with phenolic risans. Unusual lightness with great density, strength, and risstance to water absorption are among the claims made for this new naterial. It is available in the natural phenolic color and is made in sheets. Veninch or more in literies, and a maximum of 20 inches where sheet manuferance of dimerious in above story manuferance of dimerious in all sorts of weather conditions is immortant.

COMPLETE FERTILIZERS

EMPIASIS has lately been piaced on chemical elements other than natrogen, phosphorus, and putassoum in firtilizers. Numerous other secondary elements—studiur, magnesium, copper, manganese, boron, and others—are apparently notice as valid to luxurant growth of plants as the three primary certainty elements, the only difference being in the relative quantities needed, Many souls possess these secondary elements in sufficient abundance but often they must be supplied in the fertilizer.

This situation has been emphasized in recti years by some fertilizer makers with the implied suggestion that only their products contain all of these secondary elements. Now the wind is taken from their sails by a report from the Fertilizer Research Division of the U.S. Bureau of Chemistry and Soils that each of 48 samples, chosen as representative of commercial fertilizers, contain all the known scondary elements.—

House-flies Prefer

IN the Canadian Journal of Research, J. W. MacBain Cameron, of Macdonald College, Montreal, recently described experiments which were conducted with the object of testing the reactions of house-fires to different wavelengths of light The insects were

reared on an artificial medium and tested by means of different wavelengths of spectral light obtained from a quatri-mercury vapor lamp. The range of the spectrum tested waform 3022 A to 5780 A and the lines were made of approximately equal intensity throughout. The comparison standard, whis it was used in all cases, was white high to tained from a tunget of filament frosted bulk

ammen from a tingeleth nameur (rose of time). These to be lested were removed from breeding cages ten hours before the tested state of the tested that the beginn and were kept in darkans so mind used. It was found that the house fly is much more strongly animalized by ultra volte tight of wavelength 3.66 A than by any other pair of the spectrum settled. The influence does not set out to a sea as the longer wavelengths are read the day on the short wavel ought set of the peak. The stronger wavelengths are read the stronger wavelengths are read to the peak. The stronger wavelengths are read to the peak of the peak that the stronger wavelengths are read to the peak of the peak. The stronger wavelength are the stronger wavelength and the stronger wavel

AUTOMATIC FACSIMILE

THE world's first automatic telegraph was recently installed at the Essa House. New York City, according to an aunounce ment by Western Union and the hotel management. The automatic telegraph is the latest development of the telegraph conuniv's research in fassimale telegraphy.

This advance in written communication provides the assist method ever known for the transmission of a relegram, official six from the transmission of a relegram, official six from the transmission of a relegram by this method. The automatic relegram by this method. The automatic relegram by this method is the six from the six from the will, and is so simple to operate that tele-grams intrinded for transmission may be droughed into a solid method as the six from the six

Only two simple operations are required

by the sender of a telegram. First, it is necessary to push a small button, which is held until a panel reading "Deposit message" is lighted. The message is their dropped into the receiving slot face out. Nothing further is renurred of the sender.

Several sending machines may be conneeted with the same line. If one of them is busy a namel reading "Line busy" is illuminated, and it is impossible to deposit a telegram until the line is clear. Once the mesage is dropped into the machine, it is auto matically wrapped around a transmitting evlander which revolves before a photo cell and is transmitted to the main telegraph office Simultaneously, a third panel reading 'Message being transmitted" is lit When the telegram has been properly received in the main office another panel reading "Thank appears, and the original telegram is automatically "peeled" from the transmitting cylinder and deposited in a container at the bottom of the cabinet,

This type of feligraphy is made possible by the carbon-bearing fibrous paper disvloped in the telegraph company's laboratories. The apparatus is capable of transmitting 15 square melos of matter in one minure, believed to be the highest speed thus far attained in commercial facsimile (e.g.,

A RECORD FOR VIABILITY OF SEED

FROM seeds estimated to be between 300 and 500 years old, lotis plants are being grown today at Field Missenian of Natival History in Chicago. So far as can be serviamed, this represents the longest duration of delayed germination on record, actioning to Dr. B. E. Dabligner, Lucie Curation of Johann. The off-repeated story of the germination of wheat from the Egyptian properties of the p

which the Egyptian specimens were being shipped to Europe The lotus seeds had lain buried in a neat bed in southern Manchuita through several centuries, and were received through the coursesy of the University of Changas department of bottom At the time these seeds were produced by nature—perhaps before Columbus. First eversors into the New World there existed a small lake, about two square mules in area, covered with red louts flowers identical with the species commonly found in Aya today.

Records show that this lake was dramed some time between 100 and 250 years ago Wind-dirfried soil their gradually covered the ara, and trees and other land vegetation began to grow, In this beam today are large poplars, willows, and clais. One of the poplars measures from feet in diameter, and trees that have hor cut down show at least 120 annual rungs. These data on the trace and in establishing the minimum age of the bottes seeds, thousands of which have been trees grow. The lower statum contaming the seeds is a pear feel that once was the bottom of the lake.

The seeds resemble small dark brown acorns. Their coats are hard as glass and highly polished. These outer covers are so impervous that the embryos inside have been protected through the centuries.

BETTER WATER TREATMENT

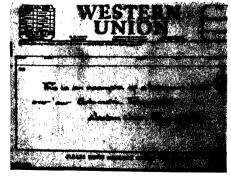

THE line-soda method of softening hard water normally fails to yield a product as soft as might be expected. The hardness of water treated by this process should be

How messages are placed in the automatic telegraph unit and, left, a received message, reduced in size

too low to be significant. However, this is not the case, and treated water retains in super-saturated solution amounts of calcium and magnesium in excess of their actual solubilities.

A new method of applying this common treatment materially reduces the hardness of treated water. The differences between the ordinary method of treatment and the improved process are apparently trifting modifications. One of these consists in mixing the chemicals for treating a fresh lot of water with shurry from water previously widing a surface for the precipitation of more salts of calcium and magnessium. The

stirring, filtering, and other operations of the treatment are similarly altered. The result is water having a hardness of 20 to 25 parts per million instead of 50 to 90, commonly met in water softened by the ordinary lune sold method $\sim D_c H_c K$

FARMERS HELP BUILD

CARS

In the production of each 1,000,000 automobiles, it is estimated that the agricultural products from a half-million acres are used. Here is a last of some products of the land consumed in making 1,000,000 automobiles and the purposes to which they are applied. 69,000,000 pounds of cotton—tires, batting, cloth, and brake lings. 50,000.

bushels of corro—butyl alcohol and starch, 250,000 gallons of molasses (from sugar cane)—solvents, anti-freex, shock shoother, and the constraints of the constraints of the constraints, and anti-rate preparations, 350,000 pounds of goat hair—meliant upholstery, 2000,000 pounds of goat hair—meliant upholstery, 2000,000 pounds of truber—several hundred parts on the motor can 112,000,000 feet of lumber—spacking and other purposes—Automobile Facet.

WITHOUT INTERRUPTING SERVICES

ANTICIPATED as a probability at the time of erection seven years ago, the all-metal office building of the Department of Public Works, Richmond, Virginia, has recently been moved 400 feet, from the corner of Twelfth and Broad Streets to a new location on Governor Street, in order that the new building of the Virginia State Library might be erected on the Broad Street site. The relatively narrow passage through which the building had to pass necessitated twice swinging through an arc of 45 degrees once before the first forward movement could be made, and the second sandwiched in between two forward movements, each in the direction of the longitudinal axis of the building.

The Public Works building is a two-story structure with full basement. It is rectangular in shape, with a frontage of 117 feet and a width of 52 feet.

The contract-time for moving the building was 60 calendar days from date of award of contract, during which time the building was maintained in a livable condition with all

Left: The all-metal office-building ready to be moved. Above: An air view taken during the moving process, showing the difficulties that were encountered

service facilities, including heat, light, telephone, water, and sewerage, without interruption to the routine work of the Depart ment or its accessibility to the public

Above the first flour, metal predomanters on hoth extror and metrors surfaces, the hasement being of masony construction. The inner and outer walls are of aluminum in the outer walls, plate and extruded shapes are employed to produce a drop-panel effective in the plasters and entablature. The inner walls, as well as the partitions and doots, but are formed from aluminum sheet. The casement walls are set as the partition are set set?

Because of the relatively light weight of the building, it was decided to move the unreinforced concrete basement walls with the building, in order to lower the center of gravity and to obtain additional longitudinal stiffening of the structure.

EMPLOYMENT

M ORE than 7500 parts from 119 manufacturing plants go into the construction of a standard locomotive, which provides employment equivalent to the work of 50 men for one year.

YOU PAY FOR MILK BOTTLES

THE cost of the bottle is a big item in A what consumers have to pay for milk. A quart bottle costs originally about five cents. Directly or undirectly, the consumer pays for it. The more trips the bottle makes from dealer to consumer, the less the cost to the consumer.

A study by the Bureau of Dairy Industry abows that many consumes actually do not realize when they destroy or discard milk bottles that the bottle has value and that it is the property of the seller and not the buyer, as is the case with most containers in which food is purchased. Education of the consumer, says the report, is too often

The Bureau in a study of 111 milk plants

found that the average life of a bottle was 3.5 trup. It ranged from sate 19 Ut rips, but the most common range was from 20 to 30 trups. The system most widely used by dealers to get bottles back are. A commission to route me not bottles returned, a charge for fall bottles sold by stores, and a mist bottle exchange, in plants that used all three methods, the average hife of a bottle was over \$1 trups.

For plants that used no special system to get bottles back and that were not members of an exchange, the bottle life averaged only a little over 22 trips.

SYNTHETIC TOLUENE

CYNTHETIC methods for producing nolumer which are independent of hyppoduct roke are being actively sought in Germany. One synthesis which has been successful on a laboratory scale uses benzene and carbon monoxide as the raw materials. Reaction between these two compounds in the action between these two compounds in the debyde from which follower can be obtained by reduction. Yields of 94 percent are reported on the laboratory scale. The value of toluren lies in its conversion to TNT, an important military explosive—D, H. K.

MAGNESIUM ALLOYS

IN AIRCRAFT

AMERICA'S supplies of magnesium are practically mexhaustible, and A. W. Winston of the Dow Chemical Company recently. They exist as magnesium chloride or as magnesium carbonate in dolomitic limestone and magnesite. It is the magnesium carbonate studies and the magnesium carbonate stall brines from wells in central Michigan which provides the nation's major source today.

Landing wheels and engine parts are the principal American applications of magnesium alloys in airplanes, Mr. Winston explained.

Landing wheels on the largest airplanes, if made of magnesium alloys, would mean a weight saving of 150 pounds, or the weight of another passenger. Thus, at present air

Relative particle sizes of three substances, all same magnification

travel fares, a plane with such wheels could theoretically save \$149.95 for each New York to I os Angeles trip, Admitting that all of this saving could not be realized, Mr Winston added, the opportunity still exists for increased payloads through weight reduction by the use of light weight alloy-

NUMBER PLEASE

MORE than 2260 tons of nickels, dimes, and quarters are collected annually from New York City's 88,000 com telephones. Ninetenths of these coms are nickels.

MINUTE COLLOIDAL

GRAPHITE

AFTER four years of experimentation, Acheson Colloids Corporation has developed a new process of producing pure "dag" colloidal graphite on a commercial scale with remarkably small particle size In the new product, the maximum size of a colloidal graphite particle is one micron (equal to 0.00003937 of an inch) with small particles tunning considerably smaller than

Colloidal graphite has for a considerable number of years been used both as a lubricant and for its electrical properties. As a lubricant its prime advantage is its affinity for metal Under friction it will deposit on metal surfaces and form a "graphoid" surface imparting to the material lubrication properties of long lasting character. Its most extensive use in the past has been as an addition to oils for running in and lubricating internal combustion engines

Formerly, however, the graphite would re main in colloidal suspension only in relatively high viscosity liquids such as petrolour oils, varnish, glycerine, water, and the

The new small particle size permits the production of stable suspension of "dag" in such low viscosity liquids as kerosene and such volatile liquids as carbon tetrachloride. An advantage gained is that colloidal graphite can now be applied to surfaces as a dry lubricant When the graphite in the light liquids is applied to a surface and the carrier allowed to evaporate, it will leave a graphitic coating on the surface, giving it cation. In addition, it seems to have definite ability to retard corrosion.

The reason that the small particles will stay in suspension, apparently, is that their mass is so small that the "Brownian movement imparted to them as a result of their negative electrical charge will keep them in continuous motion and prevent their floccu lation or precipitation.

In the heavier viscosity liquids mention suspension of the new form of "dag" has the advantage of providing much greater stability. The increased activity of the particles in suspension renders them coniderably more impervious to the flocculating tendency arising from a possible contamination of the carrier with either acids or alkalis. From a more practical standpoint, the new development promises to solve a considerable number of tough lubrication and electrical problems such as the dry Inbrication of remote and closely fitting parts, It will also impregnate porous bodies much more readily due to the finer particle size, imparting to such bodies desirable qualities of lubricity, electrical conductivity, color ing, and so on.

CATALYTIC CRACKING

ALTHOUGH thermal cracking processes.

by which petroleum is forced to give a higher yield of gasoline, save about two bilhon barrels of crude oil annually, they are likely to become obsolete in the face of a catalytic process of even higher efficiency. Thermal cracking of gas oil yields 70 to 75 percent of gasoline having an octane number of approximately 72. The new catalytic cracking process produces 85 percent of gasoline from gas oil and this has an octane rating of 81 or more. The process is said to be particularly valuable in producing fuels of high octane rating which are likely to become increasingly important. Aviation motors already require fuel of approximately 100 octane rating, and such motors are likely to become more plentiful in the future -

BUSINESS CURIOSA IN CHINA

THE China Digest, an interesting little pocket digest published in Shanghai, quotes the Shanghai Evening Post on various curious money-making and money-sav-ing schemes found in present-day Cluna: In Chungking, Szechuen province, the article claims, you are likely suddenly to find yourself being fanned by a "fan boy" who rushes up to cool you off as you walk along the street.

Also in Szechuen, "as soon as one enters a restaurant in a small town, a 'tobacco boy steals up stealthily from behind and without warning thrusts a wet tobacco pipe into

There are "toe-scratchers" who make a living in out-of-the-way towns by massaging and scratching your toes with various im-plements while you are having lunch

With the withdrawal of the Chinese government from Nanking to the interior, the custom of wearing foreign style felt hats has spread. But with it has spread the custom among the villagers of covering the hat with paper or newspaper pasted from brim to top of crown. The intention is to keep the

In combern China it is said to be difficult to buy oranges that are not peeled. The peels are highly valued for making a Chinese medicine. In Shanghai, there are shops which deal in nothing but broken glass Other shops deal only in the whites and volks saved from broken cons

RED PICMENTS FROM YELLOW

RYSTAL form has been found to be an Important factor in the color of certain pigments, and the crucial one in the valuable red molybdenum pigments now largely used in paints and inks. Actually these pigments are made by precipitating lead com pounds from solution by adding a solution of a chromate and a molybdate. Actually lead chromate is yellow and lead molyhdate is colorless when each is precipitated alone. However, when these two insoluble lead compounds are formed together the mixture is neither yellow nor colorless but red or deep orange Lead chromate normally crystallizein the rhombic system and lead molybdate crystals belong in the tetragonal system. the mixed precipitate assumes a red color only after it has been converted to the latter -v-tem - D. H. K

ROTARY WINDSHIELD

ROTARY-TYPE windshield cleaner, designed originally for aviation use, is now available for ships, small boats, trains, buses, and trucks. Air Associates, Inc., ha-

Rotary wiper in use

developed a rotary type windshield wiper which, due to speed of rotation, as invisible when in use.

The blade is carried by a driving head which passes through a hole in the glass, and is driven at any speed up to 2500 revolution-per minute by a flexible shaft from a small electric motor. Pressure on the windshield is adjustable, and the wiping edge was espe-

Close-up of the rotary wiper, showing motor head and flexible shalt

cially developed to withstand oil, gasoline, sunlight, and extreme temperatures

A special feature of the new woper a six anticining attachment. A metering pump built into the head of the dirving motor forces a special anti-cing fluid from a smill tank to the dirving head where it is distributed by centrifugal force over the area swept by the blade. This fluid prevents the former into a five on the windsheld by mixing with freezing paint. When the device is usualled on a boat, freely water can be fed to the wineto prevent the formation of salt incrination. The fluid flow is controlled by a needle valve.

It is claimed the rotary windshield cleaner is easily installed, a special tool being provided with which it is easy to drill the required hole through the glass. The flexible drive-shaft permits mounting the motor in any suitable location.

AIR CONDITIONED SUBMARINES

AlR conditioning now being installed in submarines will make America's undersea fighting force a much more potent weapon in any future war, according to William B. Henderson, executive vice president of the Air Conditioning Manufacturers' Association

The efficiency of submarines depends primarily on the fitness of those who man them and their comfort during long cruses at sea, says Lieutenant Albert R. Behnke of the Navy Medical Corps, explaining the latest submarine development.

submarine development.

The use of cooling and dehumidifying agulpment and the provision of oxygen from tanks to replace exhaled earbon dioxide will enable submarines to run submerged probable submarines to run submerged probable.

ably for periods of days, thus adding another factor to their effectiveness in attack or de-

Even with these aids, the men who operate submarines must be trained and "conditioned" for a period of at least ten days between cruises, says Dr. Behnke.

Only the fittest officers and enlisted men are chosen for submarine duty, and only about half of the Navy's personnel measures up to the stiff medical requirements.

Few persons realize the difficulties under which submarine crees work. The men musre-breathe the same air for periods of from three to 24 hours, and perhaps longer under war conditions. They must he in very cramped quarters, in which all that a sailor wors must be stored in a space about the size of his own body. A bath is something almost unheard of on a submarine at sea.

When the vessel is submerged, particularly in tropical waters or during the summer, the temperature may rise to 100 degrees, Fahrenheit, or above, and the humidity may increase to the dew-point so that aweating (which could see holdy) is impossible.

POISONS NEEDED IN HUMAN DIET

YOU need arsenie in your food. Not much of it so hitle, indeed, that ordinary chemical analysis won't detect it. But if those few thousandths of a snowflake's weight are not there you won't be healthy

The same is true for a couple of other poisonous elements, lead and manganese. These elements are present in most soils,

These elements are present in most soils, but in extremely small quantities, and ordinary tillage exhausts them, said G. Douglas Jones in a recent issue of Agricultural Engineering. To make them more available to plant roots, deeper tillage is needed. Mr. Jones is at work on several types of new soil-stirring implements. One of them, which he calls the tipper, works to depths of three feet—Secuece Service.

CLOTH FROM WHALES

WHALE must has always be n a largescale waste of the whale of industry since the carcasys of whales are commonly since the carcasys of whales are commonly left to sharks after the lubber has be n removed. Recent reports from Japan state that whale must has been successfully used to make artificial fibers, one revembing wood, and another which combines the product of whale meat with viewee having a sulk-like the moment available, but presumably include a fermentation of the most followed by a spinning operation — B HS.

CIGARET SMOKING RAISES BLOOD PRESSURE

SMOKING eigarets raises the blood pressure in both normal persons and patients suffering with high blood pressure, Drs. E. A. Hines, Jr., and Grace M. Roth, of the Mayo Clinic, found in a study of 86 persons, according to a Science Service re-

The effect of tobacco smoking on blood pressure is not due entirely to the action of a stimulus on specially sensitive blood vessel systems. Part of the effect, at least, is the result of some element in tobacco smoke which causes constriction of the blood vesselic to the property of t

Twelve mites of hard-subher piping are part of the 50 miles of pipe installed in the Industrial Rayon Corporation's plant where rayon yara are being produced by a new continuous spinning process. These pipes carry water, steam, and processing solutions, hard-vubber being used where other materials would be attacked by the chemicals. The hard-vubber pipes range in size from 11_2 to 81_2^2 inches in diameter and forms 0 are part of the 290 tons of hard rubber used in equipping the plant. Here, on special machinery, will be produced rayon yaran fainhead to exact finness and physical specifications laid downly hybrid restores.

sels. This element in the tobacco smoke was not identified in the report made by the two scientists at a recent staff meeting of the Clinic.

The rise in blood pressure following smoking was greater in high blood pressure patients than in normal persons except in the case of high blood pressure patients who had never smitched before This latter difference is attributed to the fact that mex perienced smokers do not inhale as much smoke as regular smokers.

The test was made by having each person, after a 30-minute reat, smoke two cigarets of a standard brain Blood pressure and pulse rate were wait hed during the smoking and for a few minutes afterward As a control, each person went through the same procedure except that he puffed at an unlighted eigaret

The results were also compared with irsults of the cold pressor test, in which our hand is immersed over the wrist in a bucket of rec water. This blood pressure response to this test indicates whether or not a person has an especially sensitive, or hyber-arective, isload vessel system. The excessive rises in liked pressure from smoking, the scenius's found, occurred only in the patients who had, according to the cold pressor tests, hypereroriding to the cold pressor tests, hyper-

TINY ANTI-FRICTION BEARING

A COMPLETE autofraction bearing, which, in the smallest commercial size, is no larger in outside diameter than an ordinary fointiam pen, is expected to widen the field of anti friction construction. These space-saving bearings, made by The Torrington Company, are known as needle bearings. They comprise a series of small.

Bearing compared with fountain pen

diameter "needle" rollers held within a single retaining shell Because they will carry exceptionally heavy radial loads (or their comparatively tiny size, they will permit the machine builder to apply anti-friction operation in cramped locations.

PERKS HAVE GLASS HEARTS!

THE heart of the percolator is the pump 1—and in the new Pyrex Flameware percolators it is made of a clear, stainless, sparkling tube of Pyrex glass. It never absorbs rancid odors, never discolors, and can easily be cleaned. Recently announced are a

It is claimed that better coffee can be brewed in this glass perk

six-up size with aluminum coffer basker and samiles steel fittings, and a more passe with stanless steel coffer basker and fittings. Both have the new stanless glaspump which contributes greatly to the brewing of better percolated coffer. These new percolators can be used on any heating

LUMINOUS PLASTIC.

A PLASTIC modding powder in which is incorporated a huminosi material has recently been placed on the market by a Brutish plastic manufacture. This powder, the plant is the plant in the ordinary way, yeelds up a pust which glow after exposure to strong plight. Thus, indicator buttons, figures, let-rs, and similar articles which must be found in the dark, become luminous after ters, and similar articles after must grow and a similar removal from the light worter. But the most power is a similar removal from the light worter, but the huminous property can be regenerated at will—D B R.

HAIR REMOVAL BY ELECTROLYSIS MAY BE DANCEROUS

W OMEN are warned that death may lurk in the seemingly simple electrolysis process for removing superfluous hair, in an editorial in the Journal of the American Medical Association.

The ordinary operator is likely to have httle knowledge of aseptic technique. The importance of the proper sterilization of the patron's skin, the operator's hands and arms, the needle holders, and the needles is largely unknown to these technicians or may be disregarded. Use and misuse of the machines are increasing.

Infections ranging in effect from mild to fatal may result Examples cited are pushiles, absersees, crystpelas. There is direct communication by veins between the areas of the nose and upper lip with the lateral snusses, and infections in these regions may cause death. the Journal states.

Electrolysis is also used by non-medical operators to remove moles and warts. Benign moles may become cancerous through injury Perhaps they were malignant to be-

gin with; the beauty operator and self-styled electrologist would not know

Pitting and sears frequently result from the application of too much current or too long treatment, as well as from the insertion of the needles into the hair follicle. If the operator makes several values at a single follicle or treats too many hairs in a given area, infection and serious consequences result.

According to the medical journal, the person who uses electrolyte instruments for beauty purposes should have some understanding of the following anatomy, physiology, bacteriology, antisepsis, tissue tolerance to trauma, the chemical reactions involved and the physics and mechanics of the apparatus used.— Science Service

MILEAGE

TEXAS, with its 16,000 miles of railway line, has more railway mileage than any European country except Russia, France, Germany or Creat Britain.

NEWEST VACUUM PUMPS CREATE LOW PRESSURE

THE emptiest man made space over attained is now being created by the new est vacuum pumps which use oil molecules to sweep out the air from scientific apparatus

While it is impossible to produce a perfect vacuum, a vacuum can be created in which it is possible for a molecule to travel nearly 500 feet before it would encounter another molecule.

Since a molecule is only about 0000001 centimeter in diameter, this means that in traveling 500 feet, the molecule goes more than 100,000,000,000 times its own length before encountering a companion. Here, truly, is lonelines.

If the same emptions were applied to people it will mean that a man 5.2 feet tail would have to travel more than 100,000,000 miles before meeting anyone. The lond lines would be much greater than if there was only one man on the Earth and another on the Sun

in terms of atmospheric pressures, the new oil diffusion pumps, as they are known, can

A four-compartment, three-jet Hickman non-mechanical vacuum pump

produce pressures of .00000005 millimeter of mercury without the use of cooling traps of hquid air.

Normal atmospheric pressure is 760 millimeters of mercury, which is more than a billion times that attained in the newest oil diffusion pumps.

In operation, the new pumps consist of

elaborate and beautiful glassware arranged in tubes and columns to make a complete circuit for the vapor of the oil.

The oil is heated at one point in the circuit and the vapor flows around the loop. As the flow passes a specific point, it comes by an opening leading to the chamber to be evacuated. Molecules of air coming out this opening are bumped by the oil molecules and the latter knock the air molecules away from the container being evacuated.

Dr. K. Hickman and his associates at Eastman Kodak Company developed the new pumps which are now in commercial production—Copyright, 1939, by Science Servure.

VALUE OF RUBBER

THIS year is hong orbitated the contenary of the discovery by Charles Goodsar of the process of submining public than the same of the submining public duty hased on the thermal reaction of subm with milder represent an investment of \$2.000,000 point of moless approximately \$4.000,000 point and annually use approximately \$75,000,000 points of cotton, among other tax materials— D H K

Noise Snubber

A TOTALLY new type of noise-quieting device which is non-acoustic and can be placed at any point in the intake or exhaust-system of an engine or compressor, has recently been developed by the Acoustic Devision of the Burgess Battery Company.

It snubs the slug

duced by the pulsating gases by snubbing the piak velocities and pressures and thereby produces a smooth flow of gas, this new device is called the Burgess Snubber.

Two aero-dynamic effects are involved in the operation of the Burgess Subbler, First, the fast moving dug of exhaust gas, which is vented into the exhaust system by the opening of the exhaust valve, is trapped no shigh-resistance subbling tube. This tube is perforated radially to allow the pent-up gas to vent gradually into the first subbler chamber. At the same time, a recoil pressure from the anubbing tube serves to alway the flow of seavenged gases and thereby pressure from pressure dropp allows an unsuperior pressure from place of the pressure from the pressure from place of the pressure from the pressure dropping helow amougheric pre

The abover moving scavenged gases do not enter the subhibing tube but are diverted through a low-reastance cahnust tube in the first chamber. A second stage of subbing, comparable to the first, removes any remaining impulses which may be present in the whasted gases. Back pressures can be eliminated or controlled to any desired value. The effect of the Burgess Exhaust Snubber is to prevent the sudden impact of the slug of vented gas with the atmosphere and also to stop the usual inrush of air into the exhaust pige, after the discharge of the slug. Therefore, the sharp noise of the bulg impact and the rumbling noise of the vibrating air column in the exhaust pige are eliminated.

WHERE SCIENCE ENDS HOSPITALITY BEGINS

The Waldorf, for example, is a magnificent scientific achievement, not only dependent on science when it was built, but continuously dependent on many sciences for the efficiency of its operation.

But every man of scientific turn of mind knows what we mean when we say that hospitality, in his own home no less than in the Waldorf, is something warm, living and human that survives scientific detachment.

And it is that ability to preserve the human touch, in spite of all our clockwork schedules and efficiency, that gives the Waldorf its unique reputation for maintaining close, cordial and communicable contacts with its patrons.

Besides, this year, when you come to New York, you'll get so much science at THE FAIR, that it'll be a genuine relief each day to return to the hospitality of The Waldorf-Astoria!

PERMO LIFETIME BINDER

It holds a year's issues

SO MANY readers preserve their copies year after year and have asked for binders that, after thorough investigation of binders, the editors of Scientific American found a type that is most satisfactory, considering cost, ease of handling, and durability. It holds a full year s issues 122, has an efficient patented lock; is strong and durabile; and is covered with a rich, peblider, for distillerate haustifully stamped in gold. Magazines are bound in with a same and are held positively in place; no puncting necessary. In ordering, etate what year 1998, 1993, or it is to be stamped in gold on the backbone.

Each \$1.50 postpaid in continental U. S. (\$2.00 postpaid elsewhere)

SCIENTIFIC AMERICAN, 24 West 40th Street, New York

The same type of unit is applicable to intake and output lines of reciprocating and rotary compressors. Burgess Snubbers are available in a wide range of sizes for standard, heavy duty, and spark-arresting service.

STAINLESS STEEL IGNITION CABLE

A NEW ignition cable employing a sevenstrand stainless steel conductor instead of the usual 19 strands of copper wire, has just been announced by the Sterling Cable Division of The Electric Auto-Life Company.

Breause of the extremely low capacitance
-about half that of conventional copper

Copper versus stainless steel

cables—achieved by the new construction, improvements in ignition performance result. These improvements lead to increased origine efficiency and worthwhile operating economies, according to the makers.

Low capacitance, the basic characteristic responsible for the superior performance of the cable, is a term used by engineers to measure the amount of electrical energy which all cables "absorb," and which therefore not delivered to the spark plug. The less current a cable absorbs, the lower tax capacitance, and the greater its efficiency.

Low capacitance with copper was impractical. Reducing the number of strands weak-ened the cable. Indexer insulation increased the cable diameter beyond that of the conduits on modern cars. Stanless steel, with its great tensile strength, permitted the small, yet strong, conductor required for low capacitance in a cable of standard outside diameter.

L. S. TREADWELL & CO., INC.

calls the asthenolith, or melting-spot, theory, and which he presented at a meeting of the Geological Society of America. In the April usue of the Society's Bulletin, he sets forth his theory in full or, as he himself states it, places it "on probation."

Professor Willis pictures the earth as having an outer skin or crust, a very thick, solid shell or intermeduste zone, and an inelastic, presumably molten zone. This condition, he believes, has existed throughout the entity 2,000,000,000 years of geologic history.

Professor Willis believes that throughout the entire span of grologic time, there have occasionally appeared in solid portions of the earth bodies of molten matter. Three bodies, out of which such rocks as granute were later formed, he calls sathenoiths, or melting spots. The melting, he believes, as caused by the intense heat generated when the radinactive elements present in the earth (urannum and thoroun, for example) break

An auterolatic does not remain in the spot where it was formed. It grows, and at length secreds, It may rose to the surface of the searth, and the hot moliten matter may escape from the mouth of a volcano, or it may well from the mouth of a volcano, or it may well from the mouth of a volcano, or it may well onto the from a leave for the mouth of a volcano, or it may well on the from the mouth of a volcano, or it may well be reaching the surface, and coal and crystallore at some place within the earth's cross. In one or the other of three wars much of

our grante and other works were formed. Even in terms of geologic time, the rise of an ashrenolth in exceedingly slow. Geologic transposes believe that the interval that has elapsed between such intrusions is of the order of 100,000,000 or 200,000,000 years or more. Professor Willis invites consideration of his theory as an explanation of some of the most important and striking geologic phenomena, such as the rese of great insourtains from hasins or troughs, the process cruised and control into new forms, shapes, and textures; and the activity of volcances and earthquakes.

IRON TONIC FOR TREES

Low grade iron ore, limonite, is being used to treat high lime soil to overcome chlorosis in trees. This disease is evident in the bleaching of the green of the trees leaves. Apparently iron acts as a tonic to overcome this disease.

DANGER OF FIRE FROM ELECTRON-METAL?

"LECTRON-METAL" the lightest commagnesium alloys and foot as a too to secones, as an agnesium alloys and foot as a to all pengsale from danger by fire. It is known that magnesium powder is highly flammable and is used for flash-lights and flares. Dr Voskuchlerb, nowever, who is a noted expert in this field, denied the existence of the element of danger in a attenuent made before members of the Technical Literature Society on the occasion of a tour of inspection of the IC. Dye Works in Buterleld, Cermany

Dr. Vosskuehler said that all articles made from solid magnesium alloy are in no way combustible or flammable, and that the same is true of the metal plates and waste

scraps. If exposed to extreme heat, the alloy may melt and this molten mass may burn. but the conflagration does not extend bevond the point of contact with the extreme heat. The metal shavings and scrapings which are produced when the metal is being machined can be set on fire by a strong flame and will then burn up slowly, piece by piece. Such a fire as this can easily be extinguished with dry sand. Water or other fire-extinguishers, however, should never be used to put out magnesium alloy or electron metal pieces which are on fire, as the water breaks up into oxygen and hydrogen under the high temperature and an explosion may result

Large accumulations of metal shavings and scrapings of this material should be avoided in the workshop or laboratory. The dust from this metal is also flammable just as coal dust or any other dust is flammable. and care should be taken that it does not collect. In granding or polishing this election-metal, only non-acid oils should be used These precautions apply to the workshop and factory only, as the finished article is entirely non-flammable and cannot eatch fire under any cucumstances

CCC GETS CREDIT

VOUNG men of the CCC camps were given credit for saving millions of acres of farm and pasture land, in a communication from H. H. Bennett, chief of the Soil Conservation Service to Robert Fechner director of the Civilian Conservation Corps (C C camps furnished 70 percent of the labor and to advance the soil conservation program, Mr Bennett said

In fighting gulbes, the last and worst stage of soil crosion, CCC workers have built almost 3,000,000 check dams, dug 48,000,000 linear feet of diversion ditches and seeded or solded 300,000,000 square yards of gullied land. In combating the less spectacular but more insidiously destructive sheet erosion they have planted approximately 500,000 acres, put in 18,000 miles of terraces and 41,104 miles of contour furrows, and quarried 1,403,659 tons of limestone -- Science Serme

EFFICIENT MEGAPHONE

SOME megaphones are apparently designed by reason rather than acoustics Reason dictates a long, narrow, tound "di-rective" shape, but Prof. F. R. Watson, experimental physicist at the University of Illinois, has worked out the design of a highly efficient megaphone which some might be tempted to say in advance of test would not be successful. It is short, has par allel sides and, still more surprising, it is held in a vertical position as shown in the illustration. In acoustics, things are seldom what they seem.

"Following a suggestion by Lord Rayleigh that a megaphone with a rectangular aperture could be used to direct sound, such an instrument was constructed and found effective in directing speech sounds," Professor Watson states.

"Experiments with megaphones varying in size from six feet in length to one foot led to the adoption of the smaller size for practical use This megaphone can be made of thin wood or metal; it has parallel sides, two inches apart, with a square mouth opening two inches by two inches, with an outer

JAMES STEEL MAHAN-Dopt. S. A. 201 North Wells St. Chicago, filinois opening from which the sound emerges two inches by six inches, and the length from the mouth opening to the outer opening 12

inches. "The megaphone should be held with the six-inch dimension vertical, in which case the sound spreads sideways covering an angle of more than 180 degrees When di rected at the center of a row of bleachers at an athletic meet, it sends the sound to all the auditors, including those in the end

How the new megaphone concentrates sound, wastes little energy

scats. Very little of the energy is sent vertically up or down, so that the megaphone thus places practically all the sound effectively with the auditors

"In addition to its directive property, the megaphone amplifies sound as all megaphones do It can be used effectively in auditorums, particularly in 100ms with low ceilings where hearing is difficult for auditors at some distance from the speaker. It is also useful for baseball umpires in making announcements, for military officers in directing commands to an extended group of companies, and for other similar situations

AVERAGE AGE OF EMPLOYEES Is Over 40

THE average age of employees of United States Steel companies, as reflected in group life insurance statistics compiled as of May 1, 1938, was 40.17 years. The num her of employees insured represented 97 per cent of the total number on the payroll

Employees are almost equally divided be tween those older and those younger than 40, the older group accounting for 493 per cent of the total and the younger group 50 7 percent. A total of 26,207 employees, or 13.4 percent of the entire number, are 41 to 45 years of age. The next largest five-year age group, 31 to 35 years of age, totals 25,711 employees

QUANTITIES LIMITED-ACT QUICKLY

For sale by SCIENTIFIC AMERICAN, 24 West 40th Street, New York, N. Y.

words, not more than nine pounds of pigment should be used per sack of cer Deep shades can generally be produced with less than this amount of color by judicious choice of pigments. To insure thorough mixing the pigment should be at least as fine as the cement; the finer the pigment is

ground, the greater its coloring ability.

A general guide to the selection of colors and coloring materials for various effects, prepared by the Portland Cement Association is listed:

For blue shades, use cobalt oxide. For browns, use burnt umber or brown

oxide of iron. For buffs, use yellow other or oxide.

For grays, use small quantities of man gamese black, black iron oxide, or germantown lamp black; preferably black iron

For greens, use chromium oxide, For pinks, use small quantities of red oxide of iron.

For red shades such as light brick, terra cotta, and so on, use red oxide of iron. Vene-tian red should be avoided.

For slate effects, use manganese black, black iron oxide or germantown lamp black. preferably black iron oxide Common lamp black abould not be used

Different shades of color can be secured by varying the amount of coloring material used, or by mixing two or more pigments The full coloring value of pigments can be obtained only with white portland cement,
When clear white is desired, white sand and white cement should be used. The use of white portland cement with vellow and brown sands will produce varying shades of cream, yellow, and buff. If the colors can be secured without pigments such practice 18 recommended.

TOO MUCH EARLY

ENTHUSIASM

E XPERIMENTAL results obtained by using super-voltage X rays in treatment of cancer have not justified high hopes entertained when they were introduced five yearago, Dr. Robert S. Stone recently stated in a lecture at the University of Chicago.

"Although there is very definite improvement when X-ray doses are increased from 100,000 volts to 200,000 volts, increases be yond 200,000 volts apparently reach a point of diminishing returns," Dr. Stone said.
"The 100,000-volt X rays have been aban-

doned in the treatment of all but surface cancers. But after 200,000-volt magnitude have been reached, the important opportuni ties for improvement he in devising better techniques of administering the X rays, rather than in raising voltages.

"The effect of X rays is to ionize and knock down' cells. The usefulness of the rays lies in the fact that cancer cells 'can't.

take it' and do not recover from the ionization disturbance as well as do normal tissue cells.

"It is the differential in the effect of the X rays upon the two types of cells that gives the rays any effectiveness they have. The aim of radiation therapy has been to make that differential as wide as possible, so that as little normal tissue as possible would be affected per given amount of disturbance of the cancer tissue. The danger of the increased penetration afforded by the super-voltage X rays is that they pass through one side of the body and through the cancer, and then also pass through the opposite side, injuring that tissue also.

"On the basis of the improvement in raising the voltages from 100,000 to 200,000 there should have been a slight theoretical advantage in raising them to 1,000,000 Clinically there has been none"

CASTS OF BOCK CARVINGS WITH LIQUID RUBBER

NEW and interesting method for ob-A NEW and interesting measure and rune taining easts of rock carvings and rune stones has been perfected by the Swedish Government Antiquarian Office, It consists of spraying a rubber solution over the object one or more times according to the destred thickness of the mold. The material dries very quickly, and afterwards the mat only has to be rolled from the carving. Such a mat constitutes an excellent and exact casting-mold of the carving from which it has been taken; from it any desired number of perfectly sharp and clear comes can be had.

In 1938, 10 rubber molds of this type were taken, and all turned out extremely well. This novel method seems to have doomed entirely the old fashioned system by which the carvings were reproduced by means of a plaster cast - Holger Lundbergh

COUNT THE MILES

YOU SKATE

HERETOFORE, roller skating has meant hours of aimless gliding until aching muscles told us it was time to stop. As Major Bowes might say, "we go round and 'round and where we stop nobody knows." Now for the first time we can accurately

Milenge measurer for skates

measure the distance we skate. Instead of waiting for a tired body to demand a stop, we can decide before hand how many miles we would like to glide six, eight, ten, or even twenty-and stop when we reach our "destination." This is made possible by the Skate-O-Meter, a new invention by Samuel Segal, which records the mileage covered while skating.

The Skate-O-Meter acts as one of the skate wheels and contains a series of in-

One wheel measures miles

ternal gears which operate as the wheel turns. The gears control a pointer on the dial stamped in the face of the wheel. As the wheel turns, the pointer moves to in dicate the miles and fractions of miles covered. The gear control is so adjusted that it compensates for the time the skate is off the ground. The Skate-O-Meter will record up to nine miles and then start all over again It is standard equipment on Segal Keyless roller skates, and will be marketed for use on others

FIRST NATURAL BED OF

THICK reefs of sodium bicarbonate, perbeen identified by Dr. William F. Foshag. Smithsonian Institution Curator of Mineralogy, from cores brought to the surface from depths of about 300 feet under an ancient lake bed at Searles Lake, California When holes were driven to the 300-foot level it was found that layers of almost pure sodium bicarbonate and clay alternated.

Used by housewives and dyspeptics for generations, sodium bicarbonate has always een a manufactured product, made from a base of ordinary table salt by a complex chemical process

A HUNDRED THOUSAND U. S. TANKS

IF a major war comes, the U. S. Army will need tanks by the hundred thousand, Maj. Gen. C. M. Wesson, Chief of Ordnance, warned leading automotive engineers re-cently. Now it has only a few hundred. Nearly a year from the date war is declared will be required to start mass production of the track-laying battle wagons, he predicted. Labeling an unofficial estimate of 280,000 tanks per year for war by a modern army as too high, General Wesson declared, however, "there can be no doubt that our requirements will be very large." The army is now relatively poor in tanks, having little more than enough to equip a mechanized brigade, This brigade, stationed at Fort Knox, Kentucky, is, however, sufficient for tactical experts to work out the proper ways of using the land

cruisers in time of war. Tanks are at present constructed, with the exception of certain parts, at the Rock Island, Illinois, Arsenal and not by private manufacturers because of wide variations in the number required from year to year and because the number needed is at most small. But in wartime, the resources of the automobile industry would be needed.

American tanks are among the world's hest partly because of two unique developments, General Wesson continued One of them, scoffed at at first, is the use of aircooled radial airplane engines to power the mobile weapons. This has resulted in the motor making up but 3 percent of the tank's weight, an unusually low percentage. Heavi er guns and armor plate can therefore be mounted

The second is the invention of a steeltemforced hard rubber block for the track The rubber tracks last twice as long as steel tracks, which are widely used on ordinary tractors and on tanks in other countries They also improve the tank s performance -Convergly 1939 by Science Service

GOLD-PLATED REFLECTORS AID IN DRYING AUTO BODIES

GOLD, which has found its way into obtreth, has been pressed into service to dry the enamel on your new automobile in one tenth the time required by older methods Special heating lamps, equipped with gold plated reflectors costing between five and seven dollars each, have been developed by the General Electric Company's Nela Park laboratories to line the walls of drying ovens in auto manufacturing plants

So efficient are the new reflectors -about 98 percent for the warm infra red rays- that even after operation for several minutes, the outside of the reflectors is still cold to the tone h

The new lamps, each of which consumes electricity at the rate of 250 watts, have been in service for several months in the River Rouge plant of the Ford Motor Company for which they were developed. Steam baths lutherto used take about 10 times as long to dry the car body Special electric controls turn the new heating lamps on and off in a traveling wave as the painted body passes through the drying tunnel -(opvright 1939 by Science Service

POWERFUL ANTISEPTIC

NEW concentrated antiseptic has been A NEW concentrated antiseptic has been developed which is also effective against the filaments and spores of epider mal phytons, best known in their manifesta tions as "athlete's foot." In the concentrated form the phenol coefficient is 5 against the standard test organisms, Eberthella typhi and Staphylococcus aureus. This means that as an antiseptic, germicide, or disinfectant it can be used in a dilution of 100.1.

Aside from general uses it is replacing the familiar chlorine disinfectant of the foot baths of swimming pool locker rooms Be-ing odorless, it is not objectionable and being stable there is not the deterioration in strength which usually occurs. Even at a dilution of 1,1000, it kills the filaments al though not the spores of the phytons.

The product is not irritant to the skin in dilutions below about 1:20 and for general disinfection where a high margin of safety is desired can be applied at that con-centration. It does not damage rubber or leave a deposit on the skin.

IMPROMPTH PORTRAITS

MPROMPTU portraits do not always mean "candid" in the strictest meaning of that word, photographically, A candid snap-hot is generally regarded as one taken out the subject's awareness; that is, one made without so much as an if-we-may. But there is another type of portrait, which is not strictly candid because the subject faced the camera and was shot with his consent and co-operation, but yet is not a formal portrait. Let us call this the "impromptu" portrait -taken at the spur of the moment as the photographer happens to be passing by, or while at home or visiting he decides suddenly to make a portrait then and there,

on the spot, with no preparation whatever The perfect example of the impromptu portrait is "Barney." We were going out for a picture-taking walk and stopped for a few minutes' chat with the doorman. He expressed curiosity about the miniature camera slung from our shoulder and, one thing leading to another, we stood him up against the wall near the door and shot him. The lighting was nicely diffused as it came through the glass-paned door, with the result that good modeling prevailed from the highlights to the shadows. But then one can always depend on daylight to furnish ideal lighting for photographic purposes.

The portrait of William Herrschaft, our

collaborator on the recent book, "Lighting Ideas in Photography," was taken during a full in our work on the book as we were chatting amiably and discussing the next job to be done. He was leisurely smoking a cigar. His mood was right for the picking And the camera being handy, snap came another victim.

Another time we were making some flash

shots at the judging of the most recent

Scientific American annual contest. We had flashed Ivan Dmitri, McClelland Barclay,

and Robert Yarnall Richie, the three judges,

in the act of judging the show and as they

stood chatting We had come down to our last flash bulb when it was time for the

session to call quits. The judges were leav-

ing The window panes of the elevator doors

were coated with a white, powdery "paint."

"Co. Author"

Mr Barclay came along, After some kidding, he walked over to the glass and started t draw a figure on one of the panes. As he did so, we thought of that last bulb and made the best use of it we knew, with the result that you see in one of the illustrationshown here. Before shooting, knowing that one shot was all we could have, we waited until the artist had nearly completed the figure and until his profile faced the camera, smiling and full of animation,

The other two illustrations reproduced are as nearly candid as any portrait can be. The picture of Governor Wilbur L. Cross and Charlotte Greenwood, the actress, was obviously taken when neither was aware that a camera was being pointed at them. The event was a soft-ball game involving many literary and artistic lights, including Lowell Thomas, Heywood Broun, and others. With others camera-bent we had the run of the place, and shot practically at the first show of a celebrity. As the actress approached the Governor and placed her hand on his back, comradely fashion, just before accom-panying him to one of the hall-throwing

"Barney"

ceremonies, a snapshot caught both in lovial. lively mood. An event such as this one, where the photographer can go practically where he pleases and where no restrictions apply as to what pictures he may or may not take, is heaven-sent hunting grounds for the amateur worker who is so often shunted away from subjects apparently reserved

olely for press purposes.

The shot of the singer was made on the occasion of a benefit stage performance. This one is in the true candid style, with the subject completely unposed. Nevertheless, it may reasonably be called a sort of off guard portrast of the singer, altogether different from the sort of thing one would expect in a portrait either formal or semi-formal It is a portrait of the singer in action, a poitrait of a singer's mood. The general public would look at the picture and call it a stage

Celebrities

shot; the friends of the singer might say this was her real self, the self that could not always be recorded in a straight portrait, Incidentally, the picture was shot from the front row, a distance of about 17 feet from the subject, exposure 1/2 at 1 50th

tond on fast pan film.

These are a few of the opportunities that may be met with in this connection. Many of the results will be better than anything you could get in careful arrangement of posing and lighting; many of them may

"After the Contest"

he so had they will have to be thrown away But have you not often heard the remark of the lady who said that that snapshot you casually shot as she was sitting on a bench in the park was the best picture anyone had ever made of her? True portraits are not always made in a studio or in an claborately arranged composition at home.

START WITH A TITLE

COMETIMES the remark is made about a certain picture that the caption or title under the picture put it over. However that may be, though we are personally of the opinion that a picture should speak for itself, why not try reversing the procedure and make a picture to fit a given title? It may be a word, a phrase, something you have heard or read. This is not the easiest way in the world to make a picture, but it does offer a challenge to one - ingenuity and ability to interpret an idea photographically. And after the picture has been achieved in a manner fulfilling the thought contained in your title plan, perhaps you can dispense with the title, after all, and let the picture speak for itself, clearly, and without benefit of any title.

CASH FOR KORELLE SHOTS

IF you own a Korelle Reflex, the distribu-tors of this camera are prepared to pay you "at the usual rates for exceptional shots made with this camera." The distributors, Burke & James, Inc., invite you to send them what you think most suitable, or at least write them a description of what you have. Incidentally, whether or not you own a Korelle, they will send you on request a copy of their recently completed brochure
"The Story of Korelle Reflex."

Written with particular reference to the Korelle, the brochure also has much information of general interest, discussing various branches of photography-scientific, candid, portrait, and so on,

Too MUCH OF A GOOD THING

ONE of the national photographic dealer magazines recently reproduced a photograph showing C. W. Gibbs, A.R.P.S., addressing a group of photographic fans. The picture was a flash shot which called for about a half dozen flash bulbs in order that the entire hall might be adequately lighted during the brief split-second synchronized

THE SUPER BALDINA

For Real Picture Thrills

For action, speed, split sec-ond picture thrills—the chrome finished Super Baldina is the speed camera of the age. It has the F 2 Xenon Lens in Rapid Compur shutter with speeds up to 1/500th part of a second with all controls centralized for quick, accurate and easy operation. Automatic focusing is accomplished by the coupled range finder, insuring sharp pictures always. Self erecting feature, hair trigger release, 36 exposure cartridge and other helpful points. Weighs only 12 ounces. Uses 35 mm. black and white or Kodachrome color film. Picture size 1 x 11/2 inches.

OVER \$1250 IN PRIZES

Fourth Annual Scientific American AMATEUR PHOTOGRAPHY CONTEST

Since the preliminary announcement of this contest, which appeared in our April issue, we have extended the prizes to include Third and Fourth places in each of the three divisions

Specine rules for entering this contest are given below. Please read and abide by them to insure against disqualification. You may submit pictures in any or all of the following divisions.

Division 1. Human—including portraits and other camera studies of people.

Division 2. Landscapes—including all scenic views, closeaps of parts of landscapes, seascapes, and so on. Division 3. Action—including all types of photography in which action is the predominating feature.

In each division there will be prizes of two Longines watches*—"The World's Most Honored Watch"—and two Federal Enlargers, as well as five Honorable Mention Awards

The Prizes Given for the Best Photographs in Each Division will be

FIRST PRIZE

One \$250 "Lifetime" Longines Watch
THIRD PRIZE

SECOND PRIZE
One \$125 Longines Watch
FOURTH PRIZE

One Federal #636 Variable Projection Printer (List Price \$29.50) One Federal #120 Enlarger (List Price \$17.95)

Five Honorable Mention Awards, each consisting of a one-year subscription to Scientific American

Remember that these prizes are to be given in *rach* division—or a total of six watches and six enlargers totaling \$1207.35 in value, plus 15 subscriptions to Scientific American

"Watch winners may make their own selection of pocket style or gentlemen's or lady's wrist watch

RULES OF THE CONTEST

- 1 The groups will be judged independently on the basis of pictorial appeal and technical excellence. The decision of the judges will be final. In case of a tie for any prize, duplicate prizes will be awarded to the tying contestants.
- 2 Prints must not be smaller than 5 by 7 or larger than 11 by 14 Prints need not be mounted, but may be at the contestant's option
- 3 Photographs must be packed properly to protect them during trans-
- ortation

 4 Non-winning entries will be returned only if sufficient postage is in-
- cluded when the prints are submitted 5 Each entry must have the following data written on the back of the print or mount. Name and address of contestant, type of camera, and film, chlarger and paper used.
 - 6 Contestants may submit no more

- than two prints in each group, but may enter any or all groups
- 7 Prints must be in black and white Color photographs are not eligible
- 8 Prize-winning photographs will become the property of Scientific American, to be used in any manner at the discretion of the publisher
- Scientific American reserves the right to purchase, at regular rates, any non-winning entry
- 10 No entries will be considered from professional photographers
- 11 All entries in this contest must be in the hands of the judges by December 1, 1939. Results will be announced in our issue dated February 1940.
- 12 This contest is open to all amateur photographers who are not in the employ of Scientific American

THE JUDGES:

McClelland Barclay, artist Ivan Dmitri, artist and photographer Robert Yarnall Richie, commercial photographer

> Address All Entries to PHOTOGRAPH CONTEST EDITOR SCIENTIFIC AMERICAN 24 West 40th Street, New York, N. Y.

exposure. The photographer was standing on the platform back of Mr. Gibbs and apparently had intended to make the shot athe lecturer was facing the crowd but just before the flash went off a little noise back of the speaker made the latter quickly turn around to face the photographer. As he did so, the photographer flashed the whole battery of bulbs in Mr. Gibbs' face as well as the faces of the audience. The result was a white-wash of the speaker's countenance with nothing to show where the face was but a blank paper-white emptiness. This would not do for reproduction so an artist was put on the job and sketched in Mr. Gibbs' face. And that is the way the picture stands reproduced in the magazine

No More Scratched Film

AMATEUR photographers can now treat their own films so as to render them impervious to scratches, abrasion, and finger prints. By means of a patented process that toughens the gelatin, and that can be applied at a cost of less than two cents a roll, all sizes

Vaporator

of him from 35 mm to 116 can be treated in a few minutes and with no more trouble than doing your own developing. The process is known as "vaporating" and is accomplished with the FR Vaporator, with which two rolls of film of the sizes mentioned can be treated at one time, except the 116. In the latter size only one roll can be vaporated at one time

Films are inserted into the device in the same manner as for developing and then placed in the vaporator Chemical "A" is inserted with a dropper and the cover closed After a few minutes, chemical "B" is inserted and in just a few minutes longer the films are completely treated.

The results obtained today from good cameras, skilful photography, and careful developing would seem to be worthy of this protection which should assure the maximum of satisfaction in picture taking.

PHOTOGRAPHING THE WAR GAMES

THE war games are being photographed on a larger scale than ever before, ac cording to Harwood Hull, reporting the recent Navy maneuvers for The New York Times.

"Practically every action recordable by the photographic lens," writes Mr. Hull, "whether from the air or from surface ships, has been supplied to Admiral C. C. Bloch.

"One technique carried to a new point in the war game has been simultaneous photography from two or more planes with cameras

raphy tour operating under radio control.

"These pictures will supplement the maps in telling the story of the White and Black fleets at the critique. Both maps and pictures will be seen for the first time by the nay flag and staff officers when they assemble at Countainmen.

CLEANING GLASS

WHETHER you are cleaning ground lass or plain, there is a simple bomespun procedure that will do the Job most laboragibly Just wash it with soap and wairs, first one sids, then the other, Follow with a ruse to remove the soap completely. Stand the sheet of glass so that the water runs off from one cortex. Finish the routine by suportice of ground glass will seem to smitch, going the appearance of clear glass, but this offect disappears upon drying.

TALKING SLIDE FILM DESCRIBES INDOOR PHO-

10GRAPHY

THE result of more than two years of research, a 25-minute talking side film on indoor photography produced recently by General Electric's incandescent lamp department at Nola Park is now being made available on a free rental basis to camera

From "Pictures Indoors . . ."

clubs and other groups. Entitled "Pictures Indoors with G. E. Mazda Photolamps," the new talkie is said to have been "designed to meet an urgent need for trained speakers expert in Photoflash and Photoflood technique."

Using most-technical language, the film covers the final amentals of indoor photography in more than one hundred "loos to" slide pictures. "Free use of the human interest appeal is employed," we are informed, "this lement being provided by a genial photo veteran and a candid young amateur. The secrets of successful indoor pictures are revealed one by one as the expert and movie discuss their hobby."

Starting with a description of the types, construction, and operation of the various types of Photofissh and Photolamps, the film leads the audience step by step to an understanding of indoor photographic practice. A French doll is the subject and miniature lighting equipment plus a miniature

24 West 40th Street New York City

camera illustrate the various methods demonstrated. The presentation also includes numerous examples of interesting indoor pictures taken under the lighting set-ups described. The final sequence is devoted to interesting examples of good picture subject matter likely to be found in the average

To obtain a copy, a request should go do rect to Incandescent Lamp Department (166), of General Electric Company, Nola Park, Cleveland, Ohn. The borrower merely pays transportation charges and agrees to return film and records promptly. The talkies as supplied by the nearest division sales office of the company. The borrower is also supplied with literature describing how to operate the film, where operating equipment may be obtained, and with a summary of material in the film.

NEW KODAK BUILDING

M ORE than \$100,000,000 was spent on M amateur photography in the United States during the year 1938, we learn from the Eastman Kodak Company as they an nounce the building of a new plant at Ruchester.

Nothester.

"Sales in cameras and photographic supplies shattered all records," they report,
and the year ended with a new high of
more than 18,000,000 cameras in active use

"and the year ended with a new high of more than 18,000,000 cameras in active use in this country.

"With confidence in the future the Eastman Kodak Company has announced an

unprecedented expansion program to maintain this momentum."

Incidentally, the company is dropping prices all along the camera line.

PRESS PHOTOGRAPHY

SPEED Craphic cameras are still the favorite among press photographers, judging from the fact that Speed Graphic pictures took all five of the prizes offered this year for outstanding news pictures made during 1938, including every one of the 10

honorable mentions. The awards were made at the Annual National News Picture Contest sponsored by Editor & Publisher. Craftex-made cameras have made every one of the 35 prize-winning pictures since these events were inaugurated in 1936.

The award, the Grafter Press Photography Award, symbolized by a gold, diamondstudded watch charm, went to the following photographers: Ray Howard, of the New York Journal and American, first prize for "Death on Fifth Avenue"; Howard Jones, of

Pictures and photographs become alive when seen in this marvelous optical device.

At the present time many use it everywhere.

PRICE \$2.25

Send for leaflet NU-MIRROR CO. Bridgeport, Conn. the Knoxville (Tennessee) Journal, second prize for "No Pictures"; Charles Haacker, of Acme Newspictures, third prize for "The Warde Sweide"; Ralph Morgan, free lance of Newark, New Jersey, fourth prize for "Thomas Egged Out"; and Charles Corte, of Acme Newspictures, fifth prize for "Conflagation"

The Folmer Graflex Corporation points out that the awards are given solely as recognition to price-winning photographers who make dramatic, story-telling news pictures and that clighthity for them in no way relates to the kind of camera equipment used.

PRIZE WINNER

A FEELING for composition, careful selection of viewpoint, and the most effective highting brought Eugene Lesser, 15-year-old student at the High School of Music and Art, New York, the highest honor awarded to any contributor to the second schoolastic solon of photography of the Americandra of the School of t

"Gentatrix"

can Institute of the City of New York. The preture, here reproduced, is called "Genta trix," showing the boughs of a palm tree photographed from below. The print was thosen as the finest of 308 prints submitted by 201 students from junior and senior high schools.

Young Lewer has demonstrated real aptitude in several handles of the arts and it was natural that he should carry his artistic ability ocer into photography, towards which he seems to lean most strongly. Certainly, his provides a strong argument for the need of artistic training of some sort if one is to exact the heights in photography. Neverthicraphy in first of all a mechanical art, and that until the rechangue is thoroughly acquired, no amount of art learnings or art training is going to make one a good photographer.

kodaslide Ready-Mount, When returned to the sender, the Ready-Mounts, which are made of smooth finish, specially prepared pressboard, will be numbered consecutively to correspond to the picture sequence in the film roll

The company adds that users who wish Kodachrome strips returned in the complete rolls, as in the past, may indicate this desire by clipping a corner of the address tag when they send in film for processing.

5-AND-10 NEGATIVE DRYER

VOU may have seen in the five and dime to rear a little building and the building and the little for drying small articles such as socks and handkerchefs. The gadget consists of two strips of wood each about 15 in the long and outside the current with a look similar to a cholies hanger hook. The two sticks may be swing on a horizontal plane to practically any angle in relation to each other From each stick from cholespans are superinded by small ropes, two purs on each side of the pound earlier. Altogether, there are eight of these pins. It struck us as a very handy negative dryer for the home processing photographer, sum or it permits hanging the "dryer from any handy support."

STEREO PROJECTION ROOKLET

CHARACTERIZED as "the first completely practical method of enjoying stereoscopic pictures by projection," the Stereody Polioned System of Three Dimensional Projection is fully described in a first booklet now being distributed by the manufacturers of the Lexic camera. In addition to containing a description of the vestern the booklet gives directions and hints on projecting and observing the pictures.

MONOBARH Single solution fixer-developer Developer and fixer in one bath under automatic chemical control. Inventors and manufacturers of Monobath claim negatives always develop to same density regardless of time of temperature Solution works at any room temperature between 70 and 80 degrees, Fahrenheit Choice of three types varying as to gamma and grain, and ranging from Mural Type, which is ultra-fine grain but low gamma, to Contact Type, which is high gamma but only standard grain. "Negatives cannot be over-developed in Mono-bath," the manufacturers claim "After the specified processing time of, say, 25 minutes has passed, nothing further happens if the photographer purposely or forgetfully leaves the negative in the solution for an hour or even overnight. When the image has reached full tonal value, development ceaseand fixing begins. This automatic chemical time cycle built into the formula yields definite density control without watchfulness on the part of the amateur, who is told he can now 'throw away his thermometer and clock'"

New Agea Memo (\$35) 35-mm Americanmade miniature camera. Announced by manufacturers as "result of several years"

work in refining and improving the original Memo camera which did so much to initiate the widespread adoption of miniature outfits using 35-mm film." Features "double-frame" miniature,

using perforated 35-mm film; gives 24 pictures 17/16 by ¹⁵/16 inches in size, per car-tridge of film. Equipped with Agfa Memar 1/3.5 corrected anastigmat lens focusing from 31/2 feet to infinity. New and improved type of shutter giving speeds of 1/2 second to 1/200th, bulb and time. Memo cartridge eliminates threading and simplifies loading. Cartridge supplied in four popular types of Agfa film: Superpan Supreme, Ultra-Speed

ACEA CYKON (contact) and CYKORA (projection) Parkas. Incorporate an im-proved, full scale range of tones, Intended for wide variety of subject-matter, from portraiture to pictorial and illustration work Available in several surfaces, including popular Kashmir (in white and ivory), (rystal White, Silk White, and Royal White In addition, Cykora line is supplied in Fabric White, Porcelain White, and Porcelain Ivory Both papers furnished in three grades of contrast in all surfaces. Both papers generally similar in characteristics other than speed, giving warm, black tones that may be controlled over wide range through modiboution of day lonmont or after-treatment Wide developing latitude may be obtained in standard formulas, and usual processing technique is followed

KODASLIDE PROJECTOR, MODEL 2 (\$33 50, \$52) · Compact projector for two by two inch slides, for showing 35-mm color or

"black and white" transparencies Achieves minimum bulk compatible with efficiency Base mea sures 4 by 6% inches. height of lamp hous

ing 514 inches, Base, turret head, and hous ing of die-cast aluminum with glossy, jetblack finish, contrasting with bright, natural aluminum turned finish of 5-inch lens tube Fluted sides, finished in black crackle Optical system consists of spherical glass reflector: 100-watt lamp; three condensing lenses, and 5-inch f/3.7 projection lens Special heat-absorbing glass prevents overheating slide during projection. For long projection throws, 7½-inch projection lens available. Ventilation provided as follows: "A special shell containing glass wool surrounds the lamp, Liberal space is provided inside this shell, and a similarly generous space separates it from the outer housing. The fluted exterior surface of the housing further aids in heat dissipation. In the design of the projector top, the principle of natural-draft ventilation is employed to exhaust heat rapidly, and louver strips are set vertically to insure maximum circulation. Supplementary louvers are provided over the condenser system."

Lvery day brings we scenes you'll want to record in movies. Making fine movies is easy, inexpensive, errain with Filmo 8, made by the makers of Hollywood's preferred equipment, Justicada, in, fire W bat was you get !!— in monon, at mapbab coil! Filmo 8 makes glorious color and slow-motion movies, 100 . . . indoors and out. It now costs but \$49.50—\$10 down—at all dealers. Fine 16 mm, cameras from \$76,

TO HELP YOU MAKE Retter PICTURES

FOTOSHOP, Inc. 18 East 42nd Street, New York, N. Y.

IACOB DESCHIN, conductor of our "Camera Angles' department, will answer in these columns questions of general interest to amateur photographers. If an answer is desired by mail, enclose a stamped, addressed envelope Queries should be specific, but Mr. Deschin cannot undertake to draw comparisons between manufactured products nor to advise on the purchase of equipment or materials -- The Editor.

Q. Suppose one were going to purchase an / 3.5 lens and had a choice of one from the following lenses: Xenar. Primotar, or a Tessar. Which one should be purchase and why? Will you please send me details on the above lenses as to color correction, definition, and the number of elements?---W. O. A. The lenses you mention are all of the

so-called tessar-type, consisting of four elements and fully corrected as to color and definition. Any one of these lenses will give results practically equal in quality and it would be difficult for anyone to tell from the resulting negatives which lens made which negative.

Q. I cannot find a method which will give smooth flat prints. The ferrotype plates I use give me such curled prints that I consider them useless. The method of drying them around a drum holds out fairly well, but after a few days these prints also curl. Will you please give me a method by which I can obtain flat prints or prints having a slight back curi?-K. R.

A. In a recent assue we mentioned the idea of moistening the backs of the dried prints, placing them individually between blotters and allowing them to stand in a press or under a weight overnight Also, a number of solutions are available that claim to guarantee flat prints. Glycerine in the ratio of one to 19 of water has been recommended as a sure cure for curled prints. Have you tricd using double weight papers? In any event, much can be done to prevent future curling of prints by regularly storing the prints be tween weighted papers, or in a file. One good method, though it may be bothersome and expensive, is the use of Holliston cloth backing for the individual prints.

Q. I would like a general idea of the cost of developing films at home, compared with commercial prices. About how many pictures a month would it be necessary to take to make it worth while to do such developing?-G. M.

A. We presume you are referring to the profit possibilities in photo finishing at home, for others, on a commercial basis Although we do not have exact figures, the chances are very much against the likelihood of your being able to obtain a sufficient monetary yield over and above the cost of production to make the proposition worth your while It is well high impossible for an individual working at home with ordinary equipment to compete with the large photo-finishing houses. The lates are much too low, for one thing, and an individual cannot turn out the large volume necessary to bring in a suitable return. Other factors militating against the idea include the difficulty of turning out the negatives on the 8 hour basis. the contine of pick-up and delivery, and so on. Production on a large, steady basis is the keynote of the commercial photofour-lung houses, and production is the one thing the home finisher is not equipped for

Q. I am using three Correx tanks and 312-minute developer at present. The time required to pour in and pour out the developer is apparently giving me over-developing to some extent. Ques-tion No. 1: If I added 1000 cc. of water to 1000 cc. of, say, a 31/2-minute developer, could I figure that this would give 7-minute developing time? Question No. 2: Can you suggest any way to get the most out of a thin negative for dispositive printing to prevent too much contrast? I have several hundred handcolored photographs and as many more colored by a commercial process that I am desirous of copying on Koda-chrome, Question No. 3: Have you any suggestions as to the use of "mate" to place around these colored photos in order that an exposure meter may be used, thus saving time and material? I'd like to ask the same question regarding black and white. Question No. 4: In March Scientific American you answered a question relative to copying articles from journals. You spoke of a new type of frame to hold magazines or books while doing this work. May I have information on the construction of this frame and where it may be purchased? Question No. 5: Does a piece of sheet glass interposed between printed matter or a photograph and the camera lens require extra exposure as a rule? Does it give trouble from re-flected light?—F. T. C.

A. No. 1: Dilution of the developer may

work out as you suggest but not all decelopers will work out in this way and the best procedure still is to follow the manufacturer's processing instructions. You may igure on a duration of about one minute in pouring developer into the tank and one minute fon pouring it out again, thus allow ing one minute and a half for development in the tank.

No. 2. Intensification of the negative by chemical means a probably the most effective method, permitting the intensification to protect for the minimum period required to produce a printable negative. If the negative is not bith, a medium had grade of paper contrast will give suitable results caping a yellow litter over your enlarging has sometimes is useful in printing from than negatives.

No 3 A black frame of paper or card board with an opening just large enough to display the picture is all you will need Himminate the subject evenly from both sides, each light approximately at an angle of 45 degrees to the plane of the subject Lise a meter of the so called visual extinction type and point the meter at about the center of the picture and at a distance from the subject equal to the shortest side of the meture. At this distance you will cover an angle that will include the picture only and nothing else, thus giving you the correct exposure. In view of the expense of the material you are using we would suggest that if the colored photographs are some what equal in brightness, you make a series of exposures of one of the pictures, pulling the slide of your film holder up about an such at a tune. (We understand you are using a 9 by 12 cm camera for making these color copics) Send this one Kodachrome for processing, and when it is returned you can select the proper exposure for the subject and the particular lighting set up. Concoming black and white copies, the same lighting and exposure routine as for color may be employed However, if you are to copy colored photographs on black and white film stock, it may be necessary to use a filter, perhaps a dark yellow

No. 4: The frame item to which we referred was merely a general suggestion on the construction of such a frame; the frame is not commercially available

No. 5. The use of glass in enlarging or contact printing is standard procedure. Therefore, you may employ it without hesitation. It will not give any trouble due to light reflections.

O. What is a good way to label darkroom bottles without having the lettering wash off in time?—D. L. O.

A. Every photographer has his own pet way of identifying bottles in his darkroom. One ingenious method we recently heard about involves covering the desired portion of the bottle with sulfuric acid (LP), then writing on the space with a blunt piece of aluminum. The acid is then washed off, and silvery letters are the result. This effect is permanent.

Q. In using an enamel ferrotype plate I notice that, when prints are dried, a slight raised outline of the print is left adhering to the plate which I cannot remove. This raised area sometimes is the entire paper area and is sometimes confined to the central, more slowly drying area. I would appreciate any information regarding this condition.—O. B.

A. The condition you refer to is probably caused by the presence of calcium or other impurities in the wash water need for washing the prints. We would suggest that before laving the prints down on the ferrotype plant, the prints be washful with a svecoesponge, moistened absorbent cotton, or other soft material. We presume that the ferratype plates are thoroughly cleaned with the condition of the prints are

Q. Is there some way to quicken the drying of negatives after they have been in water for an hour or so? I have used the sun and the wind on certain days to do thus, but this is not a dependable source.—E. M. W.

A Quick diving of negative can be effected by soaking in two successive halls fetted by soaking in two successive halls for mithylated spirit time ordinary commeral type; to untimine [10] percent of water, and placing in a current of air. The wind ordinary to the property of the control of the old of negative drying half also involves the start of duty being placen onto the surface of the wet emission and adhering to the latter upon drying.

Q. Is there a way of getting distortion under the enlarger without having to tilt the easel and thus necessitating the use of very small lens stops and long exposures?—S. E. L.

A Some time ago a professional photographer spoke of using a very special lens for the purpose of elongaring the image under the calager Recently, a bris of this type has been commercially introduced by the Blue Seal Products Company This lens is supplementary to the regular lens and is used over the latter The digree of clongtion provided by the lens is adjustable up to about 10 percent. The lens can be made to fit any vinlaging lens.

Q. In pouring dry chemicals out of the made-up formulas in can into the graduate I find that the narrow shoulders at the mouth of the care causes a dispersion of the material so that the latter strikes the inner walls of the graduate and is otherwise scattered. Could out suggest an efficient method of pouring from the can into the graduate that would avoid this dispersion and permit an even flow of the chemicals into the water?—I. M. K.

A. We have discovered that the best way to do this is to me an ordinary makeshift paper "funel" shaped like half a cone. Chemeals poured down this "chute" will, it is appropriately held, hit the center of the water in the graduate.

Q. Will you please give me the formula for an effective way to stop leaks in darkroom sinks?—L. B.

d. There are several methods One we head about recently seems to do the 10h what complete efficiency. The formula calls for 34 parts of asphalt, 25 parts of kerosene, and 40 parts of asbestos meal. Dissolve the asheating the kerosene. Then pour the asheating power in a little at a time until you get a stiff putty. This will provide a passet gas and prove fully waterpoor and provide and the provide of the passet gas and the provide and the

Beet is the latest steaming addition to the popular lane of hodjing 5 mm miniatures it is remainful light and compart yet is a precision instrument in exist sense of the word Among fire many features is a holl-in range finder; lone-sym bromized and optically perfect operating on the well-tamage principle. All courted parts are cash, headed and quick in a proceed for taking pictures in random sweezesion. But most for taking pictures in random sweezesion like and an input for taking pictures in random sweezesion like and in the picture in the same pictures in random sweezesion. BURLEIGH BROOKS

TELESCOPTICS

A Monthly Department for the Amateur Telescope Maker Conducted by ALBERT G. INGALLS

TUBELES's and re-embling some fanciful creature from Mass is a unque soleton Cassegranian telescope (Figure 1), built by Horace E. Dall, 166 Stockingstone Road, Luton, Bedfordshire, England In addition to the tubeless feature it has the spherical set ondary mirror, with primary figured to match, which Dall described several years ago, cally in these columns in June, 1988. At our request Dall with the property of the property of the property Dall with the property of the pro

"Enclosed are photos of my weird-looking 15½" "modified" Cassegram telescope— 'tubeless' yet framed by steel tubes. It has

Figure 1: Dall's polypedalian

turned out to be optically entirely satisfactory and will do all that a 15% can do, and that in a most comfortable manner. It is modified not alone in respect to the optical secondary—this is the less important modification. You will recall that I described beliefly the man features of the proposed alone in the function of the Principle of the Optical Secondary of the Optical

"Mainly, it consists in the introduction of a high-grade intermediate lens terreting lens if you like) between the secondary mirror 1, Figure 1, and the final image For convenence, compactives, and so on, this lens is supported by a tube 2, through the primary perforation. The benefits resulting from the addition of this lens are very great and he in many directions.

"(1) It enables the skyflooding diaphragm to be moved from the eyepoint (where it is nothing but an infernal nusance, has to be inted to each eyeptree, and is almost impossible to keep in good adjustment because of its immunic aperture) to a position between erretting lens and eyeptee where it is quite out of the way. It has a large aperture and always keeps in optical

alinement. This permits:

"(2) Wide-field eyepieces with comfortable eyepoint, greatly appreciated by spectacled observers.

"(3) A good iris diaphragm to be used for

the sky stop just described, so that the aperture of the telescope can be varied by a small index lever (as in the case of my 15'4") from full aperture down to nothing. This can be operated while actually ob-

"(4) Location of the erecting lens between the mirrors enables the long focus of the normal Casegran to be shurtened down to a very convenient length—an important feature of this 15½". I can secure the advantages of variability of the distance between lens and secondary and lens and eye piece, giving the

"(5) A final image varying in angular aperture from f/10.5 to f/26. This enableme to get a continuously variable power

over a range of 1.2½ from each eyepiece.

"(6) To accommodate any small thermal variations of spherical aberration of the primary by opposing the aberration introduced by varying the 'tube length' from the mean position for which aberrations are nil

"(7) It erects the final image, permitting excellent terrestrial views of great brilliance and completely free from any sky flooding troubles. I have a fine outlook, terrestrialls, from my observatory and find I can take full advantage of this unusual terrestrial aperture at all steady air periods, evening and morting, when air clarity is reasonable.

"In the case of the 151.5" my creting been see 23.5" in aperture and emulsise me to have an appropriate 3.6 if were 1997, and of real BFT channeler, with the see to first a BFT channeler with the whole Moon and a large margine years. This is probably unlessed of in a 151.5" ordinary Cassegran and I get it with a central obstruction of only 20 percent of the prunary diameter. (4 percent of the label.)

"The fully illumnated field is almost 0.3 degrees, but cauds into those did not not noted in at the degree of the low-power expurees. In order to get this, of course, the erecting lens is somewhat difficult and took me longer to make than the primary. Good corrections make than the primary could correction are obtained by emented triple construction and the residual secondary spectrum in the final image is quite negligible and visible only to a practiced eye.

"I calculated the eccentricity of the ellipsoidal primary and did the final figuring with the pinhole at near focus and the keat remote focus, some 120 away, the whole being quite convenient and easy. This method is the one I have always used for my spherical secondary Cassegrains.

"The driving clock, 4, is a Synclock weighing little more than ½ pound all told, and giving ample power even when I am pulling the telescope backward against the independent friction drive (between the polar axis trunnions, 5, 5, and the worm wheel).

"One great advantage of such a small motor—probably the smallest ever attempted for this aperture telescope—is that there are only one or two watts of heat to dissipate and the chance of warm air trouble in the

observatory is thereby very much reduced. "I had intended to put a pair of deflector sheets V-fashion below the optical cones to guide any rising warm air out of the optical paths, but have not yet done so-the need is not extreme, but I think it is destrable. I am certainly not troubled with tube currents, and it seems to me when comparing performance with my earlier 14", open-air, square wooden-tube reflector, that I am decidedly better off now The observalory, shielding the instrument from rapid radiation, helps a lot, despite statements I have sometimes heard to the contrary. The observatory is aluminum painted to retard rapid changes of temperature due to radiation, as per my British Astronomical Association Journal article of January, 1938

"Focusing is done principally with the little handwheel, 6, and extension shaft which moves the secondary, although additional spiral sleeve focusing can be done at the expired end

"The mittor lid is hinged and fastens back on the framework where it is out of the way (shown better in Figure 2)

"To save making up a new stand, all the lower part, 7, is an old Culver equatorial

Figure 2: Close-up of mounting

stand (date 1882). It originally carried as 81½ mirror in iron tube between the trannions but, as I couldn't get a 15½ between the same trannons. I carried it outside and put lead balance weights, 8, 0, on the other side. The overhang is thus more than one side the overhang is thus more than one would use from unfettered choice, but the whole system is very light—much lighter than the original 8½ Calver. I have added worm drives on the two axes, but I have yet to add circles and a few other improve-

"The finder, 9, is 3" in aperture and the power 10X, with an actual field of more than 5 degrees.

"The photo shows the little clock, 4, but barely shows the RA worm wheel and the

Figure 3: Dall and observatory

anti-friction rollers, 10, which I have added at each end of the 21," polar axis to reduce friction due to the polar tilt. These rollers are spring loaded and press up on the upper and down on the lower roller, respectively, with a force equal to the calculated gravity forces. A ball race takes the thrust down the polar axis.

"Other details, 11 is a handle for moving the telescope, 12 is the screw for slow motion in declination, 13 the switch for drive. and 14 the connecting box, 15 are bright and dum lamps on the dome, and nearby is the dome drive shown in Figure 4

"The observatory (Figure 3) is 12' x 12' over the brickwork base, the dome being 11' 6" in diameter, with 20 ribs Except for

Figure 4: Dome drive and bearing

the mechanical parts, it was planned and built largely by Perry, a neighbor. The dome rides on ball-bearing roller skate wheels attached to the wall or fixed base of the structure. The ash rail, which shows as a broad band traversing Figure 4, is on the dome-Perry's idea. This saves a lot of work. One of the skate wheels shows in the extreme right in Figure 4. It is mounted on a bell-crank arrangement—a triangle of iron pivoted at its upper right-hand corner. Attached to its lower corner and to the ash rail is a tension spring from an old meshtype bedspring. These springs insure that each roller carries its due share of the load, within a few percent-practically impossible with fixed rollers, Incidentally, the observed deflection of the springs in a gale enables me to judge the direction and amount of the forces due to the wind.

"To the left in the same picture is the motor drive for the dome; gears and a rubber-faced wheel. The drive is by friction and works nicely.

"The shutter of the observatory dome has a 36" opening. The flat part of the roof is covered with copper sheet."

TECH EDITORIAL SERVICE 26 West 40th Street, New York City

THE BEGINNER'S CORNER

PHOTOGRAPHY of celestial objects, especially the Moon, is one of the simplest and usually one of the first stunts performed by the builder of a telescope. The "Amateur Telescope Making" con tains definite instructions for doing it, and the equipment needed consists simply of the regular eyepiece used in visual work, to which are added some kind of box and a simple photographic plate.

On this page are shown three amateurtelescopes thus equipped The first is a 6" reflector made by Charles E. Kratz, 3115 Copley Road, Baltimore, Md., who states that the camera is made of two telescoping wooden hoves, the stationary one curved to fit the tube to which it is fastened remov ably with hooks. The sliding part has a film holder or, alternatively, a ground glass focusing screen. (Anyone who has made his own mirror will know how to make ground glass, simply by brief abrasion with mediumsized abrasive grains) Kratz' telescope is mounted on 3" pipe fittings and he says there is no shake.

The second telescope is similarly equipped and, having a worm drive, can be used for photographing the stars as well as the Moon. A. R. Karnosh, 3296 Lansmere Road, Cleveland, Ohso, is the maker.

Third telescope is the work of R. M. Watrous, M. D. and Mrs. Watrous, and is the mate to the one shown here last month, though built a little more solidly. In the Watrous telescope the same box that is used for photographing the Moon by means of the telescope may be detached, remounted as shown in the fourth photograph, a lens added, also an end to hold it, and used for direct photography of the stars. Dr. Wat-rous states that he made this 2" lens from common 1/4" plate glass and, that, though there are strike in the glass and though it is, naturally, subject to every type of aberra tion a lens can have, nevertheless it will form images-of a sort. A photograph of a part of Orion, taken with it, is reproduced. The two planetary photographs were made by H. A. Lower of San Diego, Calif., with more elaborate equipment but on the same simple principle. The first is of Saturn, exposure 30 seconds, the second of Jupiter, exposure 15 seconds. Much original detail -most of it, in fact-has been lost in the half-tone process. The lunar photo was made by B. L. Bradley, 235 N High St Salem, Oregon, and is typical of many that have been sent this department. Unfortunately, the half-tone process reduces them all good, bad and indifferent-to the same level of mediocrity but many of the orig mals received are very sharply defined

TELESCOPTICS

(Continued from preceding page)

fic Monthly, January, 1939, Prof. R. A. Millikan says that in 1900 the former "turned his attention to the problem that gave him more trouble and at the same time filled his associates with more admiration for him than any of its predecessors had done; namely, the problem of ruling very high resolution gratings. He had thought he could build a machine in a few months, or at most a few years, which would give him the desired resolution, but he spent the rest of his life without reaching the point at which he was willing to drop the problem. He often said he regretted that he ever 'got this bear by the tail,' but he would not let go, and, in spite of endless discouragements, at the end of about eight years of struggle he had produced a good 6" grating containing 110,000 lines."

Undoubtedly the note in "ATM," mentioned above, failed to lay enough stress on the supreme difficulty of this problem and a number have planned, therefore, at various times within recent years, to undertake the job For this, your scribe blames himself in large measure. This is not to say dogmatically that the amateur cannot succeed. but rather to point out the worst; namely, that the job is tough, tough, tough. It was tough even for Professor Michelson, and he was the physicist's best exponent of the methods of ultra-refinement and precision, having a marked native flair for pushing these characteristics to their very Yet this piece of work took him eight years. hence the amateur, if he undertakes it. should not do so lightly.

The ruling engine as a whole is a nice piece of instrument building but it contains one item that goes far beyond ordinary or even extraordinary varieties of nicenes the lead screw, its very heart. Making a screw is not a hard job but freeing it from errors-there is the rub. A fair glimpse into the nature of this cantankerous, pernickety job and, in fact, the only glimpse your scribe has ever been able to find in print, is contained in a six-page illustrated article in the June, 1917, number of Ma-

chinery (New York) Its title is "Making Precision Screws for Scientific Instrument and it is based on the method as used by Gaertner First, the screw is made as good as can be by ordinary methods. The job has then just begun. With a special lathe and -pecial equipment-in other words, a lot of construction has to be done before the serew can even be started—the high places due to trregularity are shaved off, leaving smaller

Figure 5: Fringes, warped flat

high places. The operation must be viewed with a nucroscope if the extremely thin cuts are to be seen at all, for the naked eve alone seems to show that the tool is not in action at all. The smaller remaining high places are again shaved off and the same process carried to finer and finer residuals The remaining steps are too lengthy to describe here. One is the testing, which is done with an interferometer, It takes the observer one month merely to test the accuracy of a screw 31/4" long. The article tells how all this is done, but not how to do it Probably no article can do that One physreist, famous for his gratings, told your scribe that, if a man had it in him he would not need written instructions, while if he hadn't he wouldn't be likely to get to first base with the most detailed instructions Sounds cynical but is probably about right Not, however, that this will scare off the aspirant-see what Porter says, in "ATM," page 651

"COME may find it difficult to make a Ronthi grating, as described in ATM, page 266, by threading the edge of a brass frame, and then winding it. I found that the sharp edges of the frame cut the fine wire How ever, no thread is necessary I made two gratings, using No 40 enameled wire (at any tadio store) The brass frame should have rounded edges and be carefully chucked in the lathe between centers, Mount a simple guide in the tool post, so that the wire is fed to the frame when it -the frame- is vertical. Set the feed at about 150 to the inch, and wind the wire on with slight tension. Before removing from the lathe, paint the edges with Duco cement and a fine camel's hair brush When div, put a thick layer of hand solder on one side only, and when dry, cut away the wire on that side with a razor blade. Do not attempt to cement the other side, as the wires are easily disturbed "-- A note contributed by Cyril G. Wates, 7718 Jasper Ave., Edmonton, Alta., Canada

STRAIN-warped surfaces on a flat ex-plains the pattern of interference fringebecause the pattern of interference Hings-shown in Figure 5, two photographs sent us by Horace H. Selby, author of the in structions for making flats in "ATMA They represent a 12" flat on an 8" disk and the chief symptom is lack of parallelism of the fringes. The appearance is exaggerated in the right-hand photograph, where the fringes are more widely separated.

INVENTION QUESTIONS ANSWERED!

SAVE TIME and MONEY Know the Rules Governing PATENTABLE Invention

INVENTORS, ENGINEERS, EXECUTIVES, LAWYERS FIND THIS A BOOK OF DAILY PRACTICAL VALUE

VITALLY INTERESTING and authortative for all who deal with invention this readable book and ready reference manual gives you the essential principles of O Patentable Invention—from 700 actual cases in the Courts! The established RULES used in determining the question of Invention—are clearly, concisely, accurately stated. Two outstanding sections in particular—What is Invention and What is not Invention make the work invalinable.

347 pages are packed with specific information on actual cases. Illuminating chapters on the Background of Insention, General Chaiacteristics of Invention, the British Rule. This splendid presentation of the legal side of invention is highly recommended to the layonan It can help you to cooperate with your attorney to greater advantage.

Dots 1. NO DUAL is a hooklet that presents a description of the modern Direct origin, what it is and how it operates as compared with the conventional gashine engine. A number of drawings make the text per feetly clear. The booklet was motivated by the recent introduction of a Direct-powered three-ton truck for heavy-duty use. It will give a wider spread to an understanding of Direct Operation and advantages, Dodge Diranon, Christer Corporation, Detroit, Michigan,—Cruits.

NYM STANDAMS AND DEFINITIONS is an 3page booklet which includes suggestions for the proper selection of electric motors and types of drives. Information is also given regarding service factors and rated doads, that will be of value to anyone who buys, specifies, or maintains electric motors. Request Bulletin No. 610. Advertising Department, The Louis Allis Company, Milwookle, Wisconin.—Oratis.

Making Up for the Camera is a 14-page booklet that tells how the photographer, professional or amateur, can obtain the best results in portraiture by having his subject use the correct type of make up. Miner's, Inc., 12 East 12th Street, New York City.—3 cents.

LEGAL HIGH-LIGHTS

Patent, Trade Mark, and Related Legal Proceedings That May Have a Direct Effect on Your Business

By ORSON D. MUNN, Litt.B., LL.B., Sc.D.

New York Bar Editor, Scientific American

UNAUTHORIZED

YOU may engage in the business of reand you may indicate in your advertising the type of automobile that you repair even though you do not operate an authorized service station. However, in so doing you must not represent that you are the authorized dealer or seeing the mainfacturer.

In a recent suit, the manufacturer of a well known automobile brought suit against the operators of a gazage or service station on the grounds that the sign that they employed created the impression that they were authorized agents of the automobile manufacturer when, as a matter of fact, they were not authorized dealers or agents. In the case in question the garage operators employed a of the type of automobile which they repaired The court found that in smaller le beneath the name of the automobile the sign contained the word "repairs" and the legend -"We . . . do not act as authorized dealers The defendants contended that the qualifying words as set forth above indicated that they were acting in good faith and that they were not trying to represent that they were authorized dealers or agents of the manufacturer. The court found, however, that the name of the automobile was the prominent feature of the sign and that the qualifying legend was relatively obscure and was not "consistent with the good faith asserted for the defendants" As a result the defendants were restrained from displaying a sign bearing the name of the particular automobile unless the sign made it clear in equally prominent lettering that the defendants were not the authorized agents of the manufacturer of the automobile

ART PATRON

WHERE an artist contracts with an art patron to execute a work of art the artist is not entitled to obtain a copylight on the work of art, according to a recent decision.

In the case in question an artist was retained by the City of New York to execute two mural paintings in one of the New York City high schools. The contract providing for the execution of the murals was silent as to the ownership of copyrights. In spite of this fact, however, the artist subsequently obtained a copyright on each of the murals.

Thereafter, without the permission of the artist but with the consent of the City of New York, s-publisher reproduced one of the mural paintings in a history book. The artist had died and suit was brought by the

artist's assier against the publisher for copyright infringement. The suit was dismissed
by the court on the grounds that the art
patron, which was the City of New York
rather than the artist, was entitled to the
copyrights on the murals and that accordnight the artist and his next of kin held the
two copyrights which were obtained in trust
for the City of New York.

In this connection the Court stated:
"When a man, hiremafter referred to as a patron, contracts with an artist to paint a picture for him, of whatever nature it may be, the contract is essentially a service contract, and when the picture has been painted and delivered to the patron and paid for by him, the artist has no right whatsoever left in it?

WASHED UP

THE use of the tade mark "Chlorn" on the cleaning and bleaching compounds has been restrained on the grounds that it is an infrangement of the trade mark "Chlorn" The manufacture of a cleaning and bleachingst compound of an interpret character it identified by the trade mark "Chora" brought suit or against a compound of an interpret character it reads mark "Chlorn," charging trade mark infringement and also infart competition.

It was contended by the defendant that the name "Cloro" was not a good trade mark and that it was descriptive of the plantiff." product since the product contained sodium carbonate and sodium hypochlorite, the late being a compound of chlorine. The court rejected this contention and held that the mane was arbitrary and fanciful and accordingly a good trade mark. The court then contained the prefages of the parties and convoluded that an anjunction should be granted. In this connection the court started:

"The selection of the word 'Chlorit' was not a mere coincidence. It was a deliberate scheme on the part of the defendants. Fortunately a Court of Equity can extend its arm to protect the plantiff in the use of the name 'Clorox'."

EARTHOUAKE

EARTHQUAKES were involved in a recent sait for parent infringement. The sait was brought against a school dustrict of Los Angeles County, California, for infringement of a parent relating to the repairing of buildings damaged by earthquakes. The patent disclosed a method of retaring whereby the damaged wall of the building was permitted to stand and a new wall was erected adiscent to and outside the damaged will. The Court found that, prior to the patent in sult, damaged buildings had been repaired by erecting a new wall made the damaged wall. Under the old method roofing or Bouring josts were carried directly by the newly erected will. In the patented method it was necessary to provide ledge-like projections on the newly errected will to support the josts, since the new wall was disposed outside the damaged will.

It was contended by the patentee that creeting the wall outside the damaged wall rather than inside and providing the ledge-like projection to support the joists constituted invention. The court in rejecting this contention stated

There, we think, are immaterial difference. This a new wall, designed to reinforce an old wall, may be creeted on either side of the old wall is, and must always have been, perfectly obvious. Equally obvious is the fact that, if a new wall, exceed outside an old wall, is to support joists previously supported with the object of the properties of the pr

DELAYED DEPOSIT

UNDER the heading, "Procrastination," in the December, 1938, issue of Scientific American, we discussed a suit for copyright infringement in which the Court held that a delay of 14 months in depositing copies of a copyrighted literary work presented the copyright proprietor from manname suit for copyright infringement.

In the case in question the publisher of a monthly magazine had affixed a notice of copyright to one of the issues of the maga zine but had failed to deposit copies of the magazine with the Register of Copyrights until after a lapse of 14 months. meantime a book publisher had published a book containing material substantially identical with an article appearing in the maga zine. After the magazine publisher had deposited the copies with the Register of Copyrights he brought suit for copyright infringement against the book publisher The lower court pointed out that the statute required that after publication two copies must "be properly deposited in the Copyright Office" and that it further provide that until this provision is complied with no action or proceedings shall be maintained for an infringement of the copyright.

Since there was a delay of 14 months in depositing the copies the lower court held that the provision providing for prompt deposit had not been complied with and accordingly that no suit could be maintained The United States Supreme Court reversed the decision of the lower court, holding that a copyright was obtained by publication of the magazine with notice of copyright and that as long as the deposit of copies was made prior to filing the suit, the publisher of the magazine had complied with the statute. One of the determining factors in the Supreme Court decision was that another provision of the statute provides for certain penalties if the copyright proprietor failed to make deposit after a demand by the Register of Copyrights. Since the statute did contain a penalty provision it was argued that in the absence of the application of the penalties provided for, the statute was sufficiently complied with when the deposit was made prior to filing suit.

Marlin Razor Blades

Old Company Slashes Selling Costs-Offers 40 First Quality Blades for Half a Dollar

The Marlin Firearms Company, famous for the manufacture of fine guns since 1870, has tound a way to bring the finest quality razor blades to shivers at a fric-tion of their usual cost

Basic patents having expired, Marlin pays no royalties. And by selling in "wholesale" quantities, with economies in packaging, shipping, etc., the company effects savings which are passed on to the consumer.

Made of the finest Swelish surgical steel, for standard holders, Marlin blades are offered at the unprecedented price of 80 for one dollar, 40 for fifty cents. Under the company's ironal adjustantee, you can try these new blades without risk. Use the best, you may return the balance and get your money back.

Mail the coupon today for a "wholesale" package f these fine blades! Mariin will pay the postage ______

The Mariin Firearms Co. 87 Willew Street, New Haven, Conn

Enclosed is for which send me postage paid, Marlin Surgical Steel Blades, Double Edge Style, under your money-back guaruntee 40 for 50s 80 for \$1

For MEN

who want to become independent in the NEXT TEN YEARS

In the Spring of 1949 two business men will be sitting in a mid-town restaurant. "I wonder what's going to happen next year," one of them will say. "My business is fine now—but the next few years are going to be hard ones, and we may as well face the facts."

The man across the table will laugh.

"That's just what they said back in 1939," he will answer. "Remember? People were looking ahead apprehensively—and see what happened! Since then there has been the greatest growth in our history—more business done, more fortunes made, than ever before. They've certainly been good years for me."

He will lean back in his chair with the easy confidence and poise that are the hallmark of real prosperity.

The older man will sit quiet a moment and then in a tone of infinite pathos: "I wish I had those ten years back," he will say

• Today the interview quoted above is purely imagnary. But he assured of this—it will come true. Right now, at this very hour, the business men of America are dividing themselves into two groups, represented by the two individuals whose words are quoted. A few years from now there will be ten thousand such luncheons and one of the men will say.

"I've got what I wanted."

And the other will answer:

"I wish I had those years back."
In which class are you putting yourself? The real difference between the two classes is this—one class of men hope vaguely to be independent sometime; the other class have convinced themselves

CONTRIBUTORS TO THE COURSE

Just a few of the business leaders who have contributed to the Institute training course are such prominent men as

Edward R Stettinius, Jr. Thomas J Watson Chairman of the Board U. S Steel Corp. Pres., International Business Mach. Co.

Alfred P. Sloan, Jr. Charrman of the Board General Motors Corp. Major B. Foster Chairman, Dept. of Business Mach. Corp. Frederick W. Pickard Vice-President E. I. du Pont de Nemours & Co., Inc

Colby M. Chester, Jr Chairman of the Board General Foods Corp.

"FORGING AHEAD IN BUSINESS" Is an interesting, helpful booklet. It is yours for the asking. Send for it. Measure yourself by it. Look clearly, for a few moments, into your next few years. Whether or not you will follow the path it points is a matter that you alone must decide

that they can do it within the next few years. Do you believe this? Do you care enough about independence to give us a chance to prove it? Will you invest one single evening in reading a booklet that has put 400,000 men on the road to more rapid progress?

This booklet costs you nothing—and for a good reason. It is worth only what you make it worth. It explains how

t you make it worth. It explains how for more than thirty years it has been the providers of the Alexan

been the privilege of the Alexander Hamilton Institute to help men shorten the path to success; to increase their earning power, to make them masters of the larger opportunities in business.

"Gee! A Nickel Left for Candy"

TOYS or typewriters, lamp bulbs or bathtubs—whenever the cost of an article is lowered through economies in production, more people can buy the article. And those who can buy the article anyway have money left to buy other things.

Take the case of the electric refrigerator. In 1927, when the average model cost about \$350, only 375,000 people bought refrigerators. But when, ten years later, improvements in design and manufacturing had brought the price down to \$170, sit times as many people bought them. And thousands who, perhaps, could have paid the higher price, were able to use the difference to purchase other comforts and conveniences for themselves and their families.

The same has been true of hundreds of other manufactured articles. Because the scientists, engineers, and workmen of industry have developed hundreds of new products, have continually improved them, have learned how to make them less and less expensive, more millions of people have been able to buy them. And by this process, industry has been able to provide the American people with the highest standard of living in the world.

In this progress, General Electric, by devising new ways for electricity to speed the wheels of industry, has played an important part. By continuing these efforts, it is helping today to provide for America still MORE. GOODS FOR MORE PEOPLE AT LESS COST.

G.E research and engineering have saved the public from ten to one hundred dollars for every dollar they have earned for General Electric

NATURE PHOTOGRAPHY AROUND THE YEAR

By Percy A. Morris

AMATEUR photographen who are looking for something new and different to do with their cameras will find here a wast and facenating field for conquest. Considerable attention is given to the equipment both necessary and destrable for nature photography, whereupon the text plunges directly into a series of 12 chapters, each devoted to the type of nature photography that can be done to the contract of the contract

April Selection of the Scientific Book Club

Science in Progress

Edited by G. A. Battell. Ten recognized leders in scientifice—permitted describe the methods and results of recent experiments. This volume, based on the National Sugma XI lectures of 1937-38, covers the fields of physics, chemistry, physiology and biology and reveals scentific rawardness in breaking down the atom, functions of chromosomes, vitamins, hormones and internal scretions, and measuring animal metabolism and electric potentials of the human house. Blustrated \$4.00.

SPARKS, LIGHTNING, COSMIC RAYS

An Anecdotal History of Electricity

By DAYTON C. MILLER author of "Sound Waves, Their Shape and Speed."

Price \$2.50

The Macmillan Co . 60-5th Ave., N. Y. C.

Books

SELECTED BY THE EDITORS

possible results under adverse conditions Birds and bird nests, insects and small animals, flowers and trees, are a few of the photographic subjects discussed. (251 pages, 6 by 9 inches, thoroughly illustrated with photographs and drawings)—\$4.20 postpaid—A.P.P.

THE CHEMICAL FORMULARY, VOLUME IV

Edited by H. Bennett

THOUSANDS of new formulas are presented in this fourth volume, which is separate and distinct from the three preceding ones. Particularly useful to laboratory and mudustial chemists, these formulas are also valuable to the layman experimenter who desires to make products used every day in the home. Comprehensive index (6.38 pages, 6 by 9)—36 to [to postaid—F D. M

PLANT GROWTH-SUBSTANCES By Hugh Nicol

CHEMISTS have discovered in recent by are substances which the gardener, the horticulturalst, botanst, and others may use to hasten the rooting of cuttings or change completely the rate of plant growth These are discoused in great detail in this volume which, generally speaking, is for the advanced student or grower, the bayman but is rather technical in spots. For the advanced student or grower, the solid principles of the property of the pr

INDUSTRIAL CHEMISTRY

By E. R. Riegel

THAT a second printing of the third edition of this valuable treatuse on industrial chemistry has been needed, is evidence of value. As a work for ready reference on industrial chemical practice it is among the leaders in the English language. (851 pages, illustrated.)—\$5.85 postpaid—D. H. K.

SCIENCE AND PSYCHICAL PHENOMENA

By G. N. M. Tyrrell

COMPACTLY, systematically, the author surveys the whole field of psychical research in a way that none has done before. His findings are guardedly favorable to a large part of the content of psychical phenomena (excluding much that seems like

sheer trickery) but he present them in such a calm, dispassionate manner that they will consume that they will consume that they will change part, of the pleadings of others for the validity of these things. It is as though some one were lecturing in a quiet, low voloce instead of the too-usual warm, eloquent manner of the expert-to-believe school. (379 pages, 5½ by 8½ mehes, unillustrated)—43.25, postpad—4.6 C.

TROUT STREAMS

By Paul R. Needham

STREAM management and trout culture are the two general subjects that are treated in this important contribution to the literature of fish conservation. Every sportsman who is interested in keeping our inland waters clean and productive will want to have a copy of this book. (232 pages, 6½ by 9½ inches, drawings and photographs.)—32 00 postpand.—A. P. P.

THE EIGHTH ART
A Life of Color Photography

A Life of Color Photography
By Victor Keppler

OLOR photography is here to stay for both professionals and advanced amateurs. In the present book the author ha gathered a tremendous amount of material and has presented it in an unusual and interesting form. First is given a history of color photography and of the various processes which have been used and which are in use today. The text then deals with the preparation of separation negatives, carbro printing, color portraiture by various meth ods, and, in more or less detail, with all of the color processes available today. The advanced amateur is by no means forgotten; a separate chapter is devoted to the technique which he should use to obtain the best results. (266 pages, 91/2 by 121/2 inches, 31 color plates, many of them full page.)-\$10.25 postpaid .- A. P. P.

QUARTZ FAMILY MINERALS

By H C. Dake, Frank L. Fleener and Ben Hur Wilson

A PRACTICAL handbook for the minral collector, with chapters on how to know quartr, its historneal lone, how it crystallizes, its crystalline, massive and intermediate as well as amorphous forms, well as morphous forms, upper, opala, perified wood. There is also chapter on the art of cutting quarts gens. (304 pages, 5½ by 8 inches, many illustrations.)—26,09 pospial — 4. C.

We can supply our readers with any of the books reviewed in this department. Prices quoted include domestic postage. Foreign prices are necessarily higher due to increased shipping charges.

OUR POINT OF VIEW

Destructive Taxation

THE publishers of Scientific American have rarely presented in its columns discussions of either political or legislative nature. In view, however, of the confiscatory terms of Senate Bill (S 1885) known as the War Profits-Tax Bill, and the fact that most of the daily press has discussed the Bill only in a brief manner. we feel impelled to present to our readers some of the specific terms of the Bill, which if enacted into law, would, in time of war, stagnate industry and pauperize the tax-payer. We do not recall any proposed legislation emanating from our elected representatives which could be more harmful to the well-being of our country than the Bill under considera tion, and it is hard to conceive why such a pernicious measure should receive seri

os consideration by our legislators. Bill S 1885 would apply the following scale of income taxes to the individual: the normal fax would be increased from 4 percent to 6 percent and a surtax rate of 10 percent would be imposed on incomes between \$3000 and \$5000 The next \$1500 of net income would carry a surtax of 30 percent; the following \$1500 of income would be taxed at the rate of 50 percent; the surtax rate on the next \$120,000 would be 70 percent; and all net income in excess of \$20,000 would be taxed at the rate of 93 percent.

If this Bill should be passed, corporations will be strangled by the imposition of a tax which is intended to limit their profis in time of war. Computation of the tax will be based on the declared capital stock values as of the year 1934 as adjusted to the end of the calendar year preceding a war declaration. Income up to 2 percent of adjusted declared value will be taxed at the rate of 15 percent; over 2 percent and not over 6 percent of adjusted declared value will carry a tax of 25 percent; all corporate income in excess of 6 percent adjusted declared value will be taxed at the rate of 100 percent.

Space does not permit a full discussion of control of the proposed Act which include a burdensome tax on undistributed profits, the filing of quarterly returns by corporations, and the length of time nor which the tax becomes effective. Neither can we go into detail regarding the personal exemptions which would be so drastically reduced as to approach the vanishing point. It is said that 50 Senators have ap-

It is said that 50 Senators have approved the War Profits-Tax Bill. and while that fact does not assure its passage, the tax-payer should take every pre-

caution against the possibility of the Bill's approval by procuring a copy of it and filing strong protest with his Senators and Congressmen -Q, D, M.

Fewer Farmers

SOME people did not even know that but country has changed from a nation of farmers into one composed largely of city workers. Those who did know this fact knew it in a general sort of way only and probably never did magnet the proportion to be; one fifth in agriculture and four fifths in city work. Few ever gave much thought to the metamorphosis or the reasons for the reasons for the

Sensational headlines are, therefore, indicated. Yet the Department of Agriculture recently announced quite casually in one of its press notices: "Why City Workers Outnumber Farmers." Not that we go in for glaring headlines or melodramatic eve-catchers We don't. But here is a subject to be picked up by the daily press and given life and color befitting its importance in the American scheme of things, For, linked inseparably to it, causing it, and benefitting by it are American democracy and the genius that made us great. Yankee ingenuity and the pioneer spirit, and the profit motive in free enterprise.

Reapers, gins, combines, corn harves; rs, tractors, and hundreds of other labotsaving devices have given greater farm production with fewer farm laborers. At the same time the expansion of industry has provided more jobs in and around cites. Improvements in distribution and processing have done their bit by assuring the farmer that a larger percentage of his produce would reach the market unspoiled or would reach a more favorable, distant market, and then, perhaps, be processed into new forms.

Technology and invention made possible or caused-depending on one's way of looking at it-this change in a nation's working habits. That, too, may sound matter-of-fact; yet it takes not even an intelligent imagination but only a knowledge of the facts of history to see bound up within it romance and heart-break, achievement and hardships. Farmers, themselves, provided many of the developments that have improved our farming methods. Others who were primarily inventors supplied many inventions. But research workers, industrialists, men with vision to see possibilities and courage to carry through have done a larger job in developing correlative services, industries, processes, and markets. Struggle has been the keynote of the efforts of all these, and some have, indeed, suffered discouragement and poverty Yet out of their work has come, not simply fewer farmers and more city workers, but an enormously improved standard of living —F. D. M.

Toward Conservation of Wasted Power

JUST as the Emily Posts of good enquette and best breeding have pracucally completed the diplomatic isolation and military encirclement of that ill-mannered, all-American habit of chewing gum with the mouth wide open, the science of psychology has extended to gum chewing full diplomatic recognition and an alliance. In a paper learnedly entitled The Psycho-dynamics of Chewing," Professor Harry L. Hollingworth, Columbia University psychologist, has announced the results of four full years of research on numerous chewing and non-chewing subjects, to prove to us what we already knew-that gum chewing raises the energy quotient of the chewer He found that writers, for example, pressed harder on their pencils, while typists typed faster. Nervous tension decreased and habits such as foot tapping drained off through the gum.

Without Emily Posts permission we have been peeking into Department of Commerce statistics on chewing gum, and we find that the industry has 26 establements employing some 2000 workers, uses about \$15,000,000 worth of materials—chicle, crude gum, sugar, corn syrup, flavoring—in making a product having an annual value of about \$50,000,000 Some \$75,000 worth of electrical energy is consumed and this represents the first or primary gum industry; what of the second?

The \$50,000,000 annual product value, which of \$0.000,000 annual product value, divided by five cents, the price of a packet of gum, represents roughly a billion purchase containing about ten billion chews. Allowing three hours per chew, and assuming the brake horsepower of the prime mover at, say, one thiriteth (although some we see look more like a full horsepower and often sound like (although some ver see look more like a full horsepower and often sound like (although some ver see look and the condition) are at the hatfour over, each year. The primary gum industry isn't a patch on this, the secondary one!

Who now will find a way to collect the wasted gum-power, return it to the gum manufacturers to be used in making more gum to release more gum-power, and so on and on—a regenerative feedback, almost perpetual motion!—A. G. I.

50 Years Ago in . . .

SCHENTOPKC AV MOERICAN

(Condensed From Issues of June, 1889)

PIGS IN CLOVER. "The value of little inventions has had a singular proof or manifestation lately in the great run on Pigs in Clover," a puzzle that has, we venture to say, here see nby nearly all our readers, for it has already made its way everywhere. Three hundred gross have been turred out daily for some time, while the de-

mand has not yet been met by the supply

AIRSHIP—"An airship designed to be completely under the control of the operator, and to be easily steered and propelled in any direction, with, on, or against the wind, is shown in the accompanying illustration... The most prominent feature of the construction is a balloon made in three comparations, the lower one stiffered to a

framework and supporting the second compartment, on which is secured the thrill compartment, exposed to the action of the wind, and with its edges attached to the framework. A closed basker, the unerror of which is partly shown, is supported on the under side of the halloon, and contains a motive power, preferably in heyeltorin, for operating sidewise Rabourg wings and central wings."

TIES—"Assuming the entire railroad system of the United Starts to be 160,000 miles, as appears from "Poor's Manual," with the addition of the lines in construction during the current year, and taking 2640 tres per mile of track, we have in use at least 422,400,000 ties. This estimate, larger though the total appears, is under the mark, as no railroad tiese-less than 2610 ties per mile, and many of the roads with though traffic have 2816, and in a few cases more."

HOBBIES.—"said a genileman who had seen much of human lifand was humself an enthusuate student at three-core years." No man in this world can be happy without a hobbly indired, for diverting our minds from the line crosses which we all have to bear, there is no earthly solace so healing as a subject in which we are intensely interested—something to which the thoughts may at any moment recur when weary of the suggestions we would escape when, in addition to being an inneered diversion, once as a useful who passes through life without being an enthusuasite student of something losses must than be can appreciate."

NEW METAL.s.—"At the last sitting of the Russian Mineralogical society, A. D. Chrusischoff demonstrated the existence of a new metal which he has just discovered, and to which he gives the name russium. It approximates clovely to thorium, and is one of the bodies whose existence was foresten by Professor Mendeleyfle We learn also that Dr. Kruss has named the metal which he has detected along with mekel and cobals, isomismis.

FLUME.—It is claimed that the recently completed San Dego flume—is the most stippendous ever constructed in the world, being only a little short of thirty-six nules long—. In the course of the flume there are soon all St reades, the longest of these being 1700 feet in length, eighty-five feet high and containing one quarter of a million feet of limiter. Another rised is of the same bright, and 1200 feet long, the man timbers used in both of these lengter by ten and eight be eight, not nogether on the ground and trased

F1,00D—"The appaling dissert of the bursting of the dam holding back the water of South Ford Lake in Pennylysians, by which Johnstown and the villages and country, near it on the man line of the Pennylsian radious duries sorp into run, well rank among the great catastrophes of the world. The English speaking race has nearly the first pennylsian penny

CRUSER.—The Italian cruses Premone was described at the meetings of the Institution of Naval Architects be her designer. Mr P Watts During a natural draught trial of four hours duration, a mean speed of 20 4 knots was attained with about 7000 indicated horse power, and during a forced draught trial of our and one half hour. duration, a measured mile speed of 22 3 knots was attained with a mean power of 12,700 hourse, the maximum power which was mainmed for a considerable time exceeding 1,900 which was four manuel for a considerable time exceeding 1,900 exceeding 1,000 miles and the property of 1,000 miles of 1,000

(ATERPILLARS.—The caterpillars, which are making their tents, carlier this year than usual, owing to the warm spring, wearing the carlier this year than usual, owing to the warm spring, weare, should be looked after at once The simplest and perhaps, on the whole, the best wav of getting rid of them is to brish off the ness-from the trees as fast as they appear, with a long handled conical-shaped brush.

TRANS CHANNEL.—"The English are contemplating an idea to lay down a postal tube between Dover and Calais. The plan is to suspend two tubes of about a yard each in diameter by means of serel calible across the channel, forty yards above the level of the sea. The steel cables will be facet to pillars at distances of about 800 yards, and in each tube a little railway will 1 um with cars capable of carrying 350 pounds in weight. No parcel of greater weight than this will be taken, and the cost is estimated at the modest future of 5000000 dollars."

TAXES are necessary—you couldn't run a city, state or government without them. But they do mount up.

Fact is, a considerable part of the money you pay us for telephone service goes right out in taxes.

Bell System taxes for 1938 were \$147,400,000 an increase of 56% in three years. In 1938 taxes were:

Equal to about \$550 a year per employee

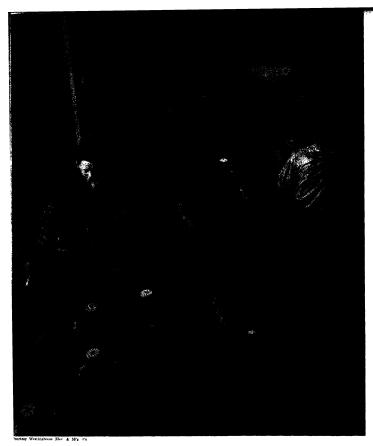

Equal to \$9.50 per telephone in the Bell System

Equal to \$7.54 per share of A. T. & T. common stock

BELL TELEPHONE SYSTEM

You are cordially invited to visit the Bell System exhibit at the Golden Gate International Exposition, San Francisco

LOW COST CURE FOR RADIO INTERFERENCE

CONVENTIONAL high-voltage pin type insulators used by power companies and industrial plants generate radio interference at line and tie wires. This is due to minute area created at the point of contact between insulators and wires. In a new type of insulator, shown above being individually inspected in the production plant, a copper-oxide glaze is formed as an integral part of the insulator and is found to eliminate the minute arcting and hence radio interference. These insulators cost no more to produce than do the conventional trouble-causing type.

The "North Carolina," most powerfully armed of all capital ships now building -a fresh note in American ship silhouette

THE FUTURE OF NAVIES

THOSE who have previously read Dr. Parker naval discussions in our pages and studied his telling wash drawings, will welcome this analysis of naval design and construction programs of World Powers. In the removemen of the Autleship terms of the Autleship the world, and in the concluding part, next month, takes up other categories.

relegances.
For many years Editor of the justly famous "Jane's Fighting Ships" annual. Dr. Parkes is respected as an authority by naval men the world over. His entre to navy departments is such therefore, as to enable him to obtain much information unavailable to other laymen. It follows that his opinions bear considerable weight.

We consider ourselves fortunate, indeed, in being able to present his two-part article to our readers. It is one of the finest in a sequence starting, Dr. Parkes reminds us, with our publication 25 years ago of his article os and drawings of the Japanese Kosechi and Kongo.—The Editor.

NOW that the Naval Treaty with its restrictions upon numbers, types, displacements, and gun calibers have been terminated, the naval Powers are free to design and arm their ships without let or hindrance, subject only to certain upper limits in batteinship tonnage and gun-caliber which have been agreed upon by the European countries; and in a world antagonized, the armament race is being pursued with the grim intensity of pre-war days although with a dread foreboding in place of national pride in pomp and circumstance. Already the alignment of forces is

Powers Build Larger Battleships . . . Sizes, Armament, Armor . . . Use . . . Effectiveness . . . Concluding Discussion, on Other Ship Categories, Next Month

By OSCAR PARKES

becoming obvious Germany, having kicked over the Versailles traces, is bent upon the formation of a pan-German league which shall dominate Europe, and the recovery of her former overseas possessions for the purpose of creating the necessary supply bases from which commerce can be attacked Italy visualizes a second Roman Empire with domination in the Mediterranean Japan aims at the complete subjugation of China and acquisition of such additional territory now held by European nations as shall make her position secure And behind it all is the necessity for foreign tradetrade assured by the national possession of great markets which may be closed to competitors-and sources of natural wealth from which the basic necessities of industry may be obtained without cur-rency difficulties.

N ATURALLY both Britam and France would be content with the satutax quo, but as the ambitions of Germany and Italy can only be realized at the rapense of these two democracies, they have been compelled to "look to their mosts." America sees the probable loss of her trade in the Far East—the future greatest market in the world—with the possibilities of pro-German trouble in South America and must needs remember that she may become involved in defending her interests in both the Atlantic and the Pacific. And so while Japan, Germany, and Italy can plan their forces with the

object of attack, Britain and France must visualize the fair more difficult problem of world-wide defense. America, having neither overseas possessons to tempt the Have-nots' nor the problem of guarding an ocean-borne food supply, is in the happer position of being able to concentrate her energies upon what is recognized as the best form of defense.

Having this outlined the ambition active or passive—of the Powers, we are in a position to appreciate the composition of the naval forces being amassed by each, and such peculiarity of type or design in the various classes of fighting ships as has been dictated by particular national requirements.

At the present time, history is going through a phase of repetition. Fifty years ago the battleship was popularly sup-posed to have become obsolete owing to the growth and alleged effectiveress of torpedo craft, and her place was to be taken by fast "protected" cruisers. The later development of quick-firing guns enabled the big ship to assume her rightful place as the prime unit of naval defense Then, for some years after the World War, her pride was again humbled, this time by the submarine and airplane which, in combination, should theoretically have been able to drive the goliaths of the sea into impotent seclusion; but the inevitable development of defensive measures again assured their supremacy afloat, although to a more qualified extent.

Today, the measure of a battleship's powers of defense against air and underseas attack depends largely upon her displacement. Given sufficient beam, a ship can have enough bulges and internal longitudinal bulkheads to withstand several torpedo hits; given the weight of deck armor, she can be made to withstand heavy bomb attack. No ship can be made impregnable, but "the bigger the safer" is a sound axiom, and if very big guns are to be carried as well as an adequate secondary armament, certainly more than 35,000 or 40,000 tons will be necessary-at least 50,000 tons is regarded as the constructor's datum line. With such a displacement, the battleship will become a fanta-tically expensive weapon, with limits to numbers and an undue national value attached to each--loss of one meaning a catastrophe impossible to overcome during war.

Can the monster battleship he replaced by other types of warship—or by artcraft? So far as the Brush Admuralty is concerned, the answer is in the negative In collaboration with the Air Munitry, the whole question of relative cost and upkeep with a given finant ial outlay has been thoroughly investigated and they have agreed that the present cost of a hattleship can be represented by 32 twin-engined medium bombers, taking into consideration the overhead, maintenance, replacement, and similar charges to make an effective comparison during the life of a capital ship.

Actually, the relative costs of battleships and airplanes have not, in themselves, any bearing upon the matter If capital ships are essential to security, they must be provided; the advocates of air power would wish that their country should build no more—although other Powers should still continue to build them. If their theories turn out to be well-founded, unoney has been wasted; if ill-founded, the test of them would result in the loss of perhaps are emitty.

How, then, are battleships likely to be employed in future warfare? In the past they were used: (1) on blockade: (2) to cover landing operations; (3) for hombardment; and (4) to bring the enemy fleet into action. Today submarines and aircraft will put (1), (2), and (3) out of court: these duties will be relegated to lighter craft and the battefleet will exercise its influence only as a distant covering force But, whereas commerce rading, and convoy protection were formerly essentially cruiser duties, in future hossentially cruiser duties, in future hosmaking the problem of commerce protection microscipily difficult and commaking the problem of commerce protection microscipily difficult and compleated. Naval warfare will turn more and more upon the attack and defense of vessel being employed, the battleflect vise playing an active or expectant part as a the attacking forces utilize their capital. Shues as constant.

THE present growth in battleship ton-nage, as shown in this present review of 35,000 tonners being built by the Powers, is due to Japan's having withdrawn from the Naval Conference two years ago When she intimated her unwillingness to continue the exchange of naval information or to adhere to the limitations in displacement hitherto observed by the Powers, it was generally anticipated that her intention would be to enlarge her battlefleet by the construction of ships of more than 35,000 tons-which was the agreed limit-and with her predilection for the heaviest guns, everything pointed to an increase in their carrying weapons of more than 14-inch caliber. In due course it was reported that three or four 40,000 tonners carrying 16-inch guns had been laid down, and as neither confirmation nor denial of this was vouchsafed by the Japanese authorities, there was no other course open for the United States and British Governments but to conclude that this information was probably correct and to increase the dimensions and armament of their new ships accordingly.

On the other hand, it must be remembered that the Treaty also provided that no warship other than a capital ship should carry a gun of greater caliber than 8 inches-which precluded the construction of a variety of intermediate types such as the German Deutschland and light battle-cruisers. This was provision simplified design and eliminated the risk of existing types being comprovision simplified, But today the snottly of Treaty designs no longer obtains than the provision should be such as the such as the same types of the such as the such

ing upon a vastly expensive big-ship program. Her secrecy may be an excellent cover for what might prove a far more troublesome Treaty escape—the con-struction of "intermediate" ships. In the past, she has complicated the accepted categories by such ships as the 12-inch gun, armored cruisers Tsukuba and the larger Kurama of 1905; and after the War when introducing the 8-inch gun in the Kako class (1922) she initiated the Washington cruisers-which were neith er wanted nor welcomed! Today, it is quite in the cards that the 40,000 tonners are a blind and that fast, 12-inch-gunned ships of moderate tonnage are being built. If so, our troubles in Eastern waters will be considerably increased as such ships would be able to smash up the standard 8-inch gun cruisers and escape from any of the 21-knot battleships which are at present available and which cannot be reinforced by faster capital ships for some years to come.

The American answer to the Japanese challenge is a class of six 35,000-ton ships of the North Carolina class now being built under the 1937-38 programs. They carry an armament of nine 16 inch and 20 5 inch guns, with two triple turrets forward and one aft, with the secondary guns-of which eight are reported to be 5-inch, 25-caliber anti-aircraft-grouped in small turrets amidships. To a large extent they represent the conventional layout observed by all the Powers except France. Formerly, it was customary to break the hull line by a deck at the after superstructure and space the sec ondary battery along the upper deck side or along the superstructure deck in casemates. Nowadays the demands for high angle fire and wide arcs of training have led to the adoption of small turrets on two levels to avoid interference. In the North Carolinas, four of these are on the weather deck and six on the superstructure, with multiple anti-aircraft positions high up on the fore and aft shelter decks. At the stern are two catapults with a hull hangar as in the Brooklyn cruisers an admirable arrangement if practice bears out theory.

In these day's when so much information is confidential, only a general idea of armon thickness is available. This indicates that the waterline belt is of 16-inch armor amidships from the fore to the after turreta, with a six-inch upper day and a four-inch lower deck—the-se being very heavy to withstand plunging fire from hig guiss and heavy bomb

Italy's "Littorio" and "Vittorio Veneto," to be ready this summer the first of the 35,000 tonners being built by the Powers. For a time they will be most formidable ships affoat

All illustrations drawn by the author H M S "King George V," of a class of five now building. Note secondary guns paired in shields athwart funnels

The designed speed is reported to be about 28 knots, in which case the class will be about two knots slower than the British, French, and German 35,000 ton-ners. However, as they carry 16-inch against 15-inch or 14-inch guns and are specifically designed to meet the Japanese battleships of alleged greater ton-nage with 16-inch weapons, the sacrifice of speed as that which can best be afford of an compromise of military and nautical qualities. Nowadays no figures of fuel capacity are officially supplied, but these ships should have a maximum of well over 4000 tons of oil

As the cage mast gave way to the tripod, and that, in its turn, has been superseded by the bridge-and-tower structure of the Idaho class, so in the North Carohng a new type has been evolved: a truncated cone supporting the heavy range-finder which resembles the "mast favored by the Germans Aft, there is a light pole only-the remnant of a main mast which is now just a hindrance to sky-fire. A glance at the layout of previous battleships will show to what an extent their after tripods or cages mask the anti-aircraft guns on any off-side ceiling, and the present tendency is to afford as wide and as uninterrupted a field as possible to anti aircraft defense

In Britain, two classes of battleship are now in hand: the King George I', and the Lion The former, designed in accordance with Treaty limits, is of 35,000 tons and armed with 14-inch guns. No dimensions have as yet been published, but the length is about 750 feet as in the United States' ships; and the main armament of ten guns is carried in three turrets; a quadruple and a twin superfiring forward and a quadruple aft. This is a complete breakaway from the Nelson layout with its three turrets up forward, and allows for a good all-round concentration of fire. Instead of the customary 6-inch gun for secondary armament, a new gun of 5.2-inch has been adopted. Sixteen of these are carried in four groups of twin turrets, the inner guns being raised on small separate superstructures. Multiple pom-poms are mounted on the crowns of B and C turrets and on platforms abreast of the four funnel, which allows for wide ares of sky fire. Other antistratif gims are disposed on the superstructures. On deck between the funnels is lad at histoshipe-catapult with langars for four arcraft on each side of the fore funnel, the cranes for handling both arreaft and boats being stepped on the after superstructure Between the end turets, there is a belt of 16 inch aimor, tapering to 15. meh, reaching up to the main deck, and over 11,000 tons of armor have been distributed over the sides and decks. Unofficial reports erieft a speed of 30 knots with 13,0000 hors nower.

This class will be retained in European waters when they are commissioned in 1910 and 1941.

N then four vessels of the Richelten class, the French have retained the characteristics of the previous Dunkerque (26,500 tons, eight 13-inch guns), enlarging the hull to the 35,000 ton limit in order to carry eight 15-inch guns. These are in two widely separated turrets forward, in each of which are two pairs of guns separated by an armor bulkhead a disposition permitting a heavy concentration of fire forward and just abaft the beam but powerless to engage an enemy on the quarter or astern Although this is admirable as an offensive distubution of turrets, experience during maneuvers with the British Nelson and Rodney has demonstrated its dangers, and in a running fight with the enemy astern these ships were unable to return

The 15.6 inch guis which will form their secondary animanent are in five triph turrets, two on each side and one on the center-line over the hangar aff Between these are two 3.9-inch antiaircraft guis and a larger number of smaller sky guis are distributed over the superstructure. Four planes are stowed in the hangar which extends onto the quarter deek, with two catapules.

Nothing so imposing as the bridgetower has ever been erected on any warship. As now contemplated, it will be a huge, almost triangular, structure with the blanted apex forward carrying a crown of range-finders. In the British $King\ George\ V$, the tower contains the conning tower; in the French Richelieu, this is seen rising through a two-decked bridge at its forward base. In the drawing, note the searchlights on control towers alterast the funnel and the curious pagoda of controls, aft, from which arises the main and

The total weight of armor is just over 15,000 tons, the heaviest proportion to displacement yet assigned to any capital ship so far as is known. From the forward turret to the after 6-meh triple. the belt is 16-inch with 9-inch continnations to how and stern turrets are 16 inch face and 14-inch side armor, and the upper and lower armor decks total 8 inches-a truly wonderful carapace against vertical attack! With but six high-pressure boilers, the horsepower is 155,000, giving a speed of 30 knots and more, the funnel so close to the tower is likely to prove troublesome in a following wind. The Richelieu will be ready in 1939, the Jean Bart in 1940, and (lemenceau and Gascogne in 1941.

The present rapid increase in the German Navy is now of especial interest in America as the Chancellor aims at regaining the former colonies of the Reich which would allow for the development of naval bases on the west coast of Africa within striking distance of the American continent In the event of a successful campaign in Europe, this aim might be achieved, in which case an alliance with Japan would consolidate the German plans to extend her interests in South America. For the present, there is an agreement by which the Reich limits the construction of surface vessels to 35 percent of the British Navy with an elastic interpretation as applied to the submaone arm. But Germany has learned by experience that in a short war she would not need to have command of the sea so far as surface ships were concerned; a big and efficient submarine fleet would play more havoc with the British Empire than a ratio of more than 35 per-cent of battleships and cruisers. And present-day German strategy does not aim at keeping a great fleet standing by

The German 35,000 tonners, no building, have immense beam and massive protection. Absence of main must permits anti-aircraft cross-fire

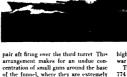

France's "Richelieu" has two quadruple turrets of 15-inch guns. Note great conning tower surrounded by bridgework, and huge tower mast supporting the control positions aft

in North Sea harbors for coast defense purposes. Her new capital ships are to be sent out in company with carriers and cruisers to prey upon shipping, and the main problem of the British buttle fleet will be to try to prevent such forces from shipping through the northern exits from the North Sea in fog and darkness

For this reason she has given her Scharnhorst and Gneisenau, just completed, a speed of 27 knots, and aims at 30 knots or more in the 35,000 tonners now building. Both Germany and Italy are responsible for introducing high speed into battleships, thereby greatly increasing their size—as speed demands length unless power is to be increased out of all proportion to displacementtheir cost, and their individual asset value. The first of these 35,000 tonners, the Bismarck, was launched about four months ago and the second, the Admiral von Tirpitz, on April 1; the third was laid down last year; and a fourth is projected and likely to be commenced during 1939. They will be 792 feet long -40 feet longer than the American and British designs—with the colossal beam of 118 feet and only 26 feet mean draft to allow for shallow North Sea work. Such a beam means immense docks but will permit of under-water subdivision never before attempted, which should give near-immunity to torpedo attack.

Under the Versailles Treaty, the biggest gun permitted in the German Navy was 11 inches on a displacement limited to 10,000 tons. These restrictions produced the famous Deutschland class, able to outsteam all battleships and outgun all cruisers. In the two Scharnhorsts, just completed, displacement was raised to 26.500 tons to provide adequate protection for a hull carrying nine 11-inch guns as a main armament Hence they will be able to work in concert with the Deutschlands and utilize the guns already built.

In the new 35,000 tonners there was no question of following the British example with 14-inch guns, and in a single step the Marine Amt decided to go one better than the King George V class now building. There will be two turrets fore and aft carrying 15-inch guns with 12 6-inch guns amidships in four twin- and four single-gun positions. Fourteen 4.1inch anti-aircraft guns are to be spaced a deck higher, six aside amidships and a

vulnerable; it is possible that the catapult will be moved to the quarter deck to

allow for more generous spacing of the

smaller guns. The Germans favor a moderate freeboard with a marked sheer towards the laws, and are "small-target" ships. Geared turbines, in combination with Diesels and very high pressure boilers, allow for a single funnel with a broad trunk base around which is built a searchlight platform serving as a support to a light tripod pole must for the radio aerials. By keeping the rig forward of amidships, the anti aircraft guns have unobstructed arcs of sky bearing, which is really only evident upon observation from the decks of the Scharnhorst or Leipzig

NO details as to protection are available, but it may be taken for granted that the armor allowance will be as generous as in their contemporaries and fully utilized to the last ton and maximum ad-

After considerable delays, Italy's first modern battleships, the Littorio and Vutorio Veneto, will be ready for sea this summer and their trials will be watched with considerable interest as their engines are designed for 160,000 horsepower-the highest ever installed in warships barring the U.S.S. Saratoga and U.S S. Lexington. This power is intended to realize 32 knots, and Parsons geared turbines have been installed instead of the Belluzzo type fitted in battleships recently reconstructed. Such a speed makes the category of "battle cruiser" superfluous, and is in keeping with the very high rates of steaming recorded by postwar Italian cruisers and destroyers.

The four ships of the Littorio class are 774 feet long with a beam of 103 feet and a mean draft of 28 feet, giving the standard displacement of 35,000 tons common to all the battleships under review. The three turrets house triple 15 inch guns, and at the four corners of the superstructure are smaller triple 6-inch turrets, with three pairs of 3.5-inch, anti-aircraft guns between them. Twenty smaller sky guns are carried and may be seen nested on the turret crowns and hangars. With such an armament and speed, there has had to be some sacrifice in protection so that the main belt is reduced to 9 to 12-inch, and the turret and deck armor should be proportional to this.

The foremast is a cone crowned by the big range-finder and surrounded by bridgework, with an unusually heavy tripod aft carrying searchlights and antiaircraft guns; abreast the fore funnel are the hangars, with catapults along the edge of the hoat deck amidships. Italian constructors now favor two funnels when possible, as a bad hit on a single stack would seriously affect furnace draught and these two ships, with the Roma and Impero now on the stocks, will have the same general profile as the four reconstructed Cavours, the funnels being of unequal height with cutaway black caps which are said to assist in keeping the fire control clear of smoke in a following wind.

Presumably intended for hit-and-run operations, the four ships of the Littorio class will present a very serious problem in the Mediterranean although it is anticipated that Italy will depend upon small craft rather than expose her bat-tleships to the risks of a fleet action.

How METALS RELAX

Research Engineers Demonstrate that Metals Stretch and Lose Their Grip with Time and High Temperature

C TEEL bolts and rivets creep and relax, research engineers have reported at the conclusion of a three-year investigation at the Westinghouse Research Laboratories.

The investigators have invented an au tomatic relaxation machine which determines within a few hours how much metals will relax in many years. Engineers A. Nadai and John Boyd have been heating, stretching, and "relaxing" copper and steel to discover how and why bolts eventually lose their grip under

high temperatures.

This habit of metals to relax has long been a problem in great steam turbines where heat is converted into power to run the machines of the modern world. The problem comes closer home to the average person when the garage man findthat the bolts in the motor head of his automobile are loose. The unseen cause of the loosening is creep and relaxation resulting from the heat of the automobile engine-two phenomena characteris-tic of all metals, particularly at clevated temperatures.

"So far as we know, there exists no metal which does not display this deformation characteristic," observed Dr Nadai, "If sufficient time is allowed, all metals and any other solids will creep or deform under continuous loads, even at low room temperatures."

When an engineer designs a steel bridge, he can calculate the stress and strength of the steel and know how his bridge will be able to carry a definite load 100 years from now. But when an engineer designs a steam turbine, he must take the effects of heat into consideration because the temperature will determine the effective life of his machine. Temperatures have steadily climbed upward in modern steam turbine applications until today the steam pipes of a turbine in a modern central power station start to glow at heats of more than 1000 degrees, Fahrenheit.

But if the steel used does not creep

more than one one-hundred-millionths of an inch during every hour of the life of the steam turbine, the engineer is satisfied that its life expectancy will meet present practical requirements. This "permissible" amount of creep figures out to be one one-thousandth of an inch over a period of ten years. When a bolt is tightened into place, it is actually stretched in the tightening process since a stress som times as high as 60,000 pounds to the square inch is applied While held in this position the bolt is not permitted to contract but its stress gradually decreases; that is, the bolt relaxes its hold in time.

Consider a spring as another illustration. When it is stretched out and released. it springs back to its normal position But if the same suring is stretched and then heated at a high temperature, it will not

spring all the way back to its original position It has been permanently deformed and its clastic strain has been gradually transformed into a permanent plastic strain or deformation

The investigators used copper bars in attempts to discover the secrets of relaxation. They selected copper for the first tests because of its importance in electrical machinery and its purity as a metal. They loaded the test pieces with weights, maintained the temperature in the room at 77 degrees, Fahrenbeit, and charted the amount of stretch.

NEXT, identical test bars were placed in a relaxation machine where, this time, the load was automatically lightened to maintain the bar at a constant length. It was discovered that the results of the creep test and the relaxation test could be closely correlated. Thus it is possible to predict the rapidity of copper's relaxation at room temperature by studying the creep, or vice versa.

At room temperature, copper will hold its own for a good many years without appreciably losing its grip. On the basis of these tests, the investigators calculated that a copper bar starting with a stress of 19,850 pounds to the square inch would relax only to 12,600 pounds of stress in a 20-year period, provided the temperature did not exceed 77 degrees.

But at a temperature of 350 degrees, Fahrenheit, copper would relax from 19,200 pounds stress to 2000 pounds dur-

Examination and adjustment of electrical con

ing this same period. The relaxation was so rapid that the test bar would be unloaded perhaps after a few minutes if the temperature were shot up to 500 degrees, Fahrenheit.

Even steel, much harder than copper, would relax 60 percent from an initial stress of 11,750 pounds if maintained at a temperature of 850 degrees for 20 vears, the tests disclosed.

Several additional experiments showed that by frequently retightening a steel bolt when it became loose, it was possible to strengthen it and increase its resistance to relaxation.

These discoveries have convinced Dr. Nadai that "our engineers must find the new laws" underlying the phenomena of creep and relaxation, "if the engineers are to continue their steady advance in making steam turbines ever more effi-cient power producers." He pointed out that "the theory of elasticity is the base of all engineering design now taught in the schools, but no adequate theory of creep yet exists."

Both men expressed confidence that the invention of the automatic relaxation machine is a step toward creation of such a theory. The apparatus is so designed that a metal test sample is weighted by a spring which is stretched by a worm drive connected to a motor. While an electric furnace heats the test piece, sensitive electric contacts operate the motor to adjust the load and maintain the sample at a constant length despite the stretching of the metal.

he first step in the process is the pouring of sample from the molten metal into a hand mold

Controlling

THE method by which actionomess discovered helmon on the sun before it was known to exist on the earth has been put to work to hip make betterabley from an steel in the Ford Motor Company's Goundry. The method is spectrographic analysis, and it enables the metallingists to know that each 'heat' of the metal is right before it is pouted of the metal is right before it is pouted.

The new analytic method has been in operation long enough to show that it is both faster and more accurate than the chemical method it supplements. It quickly shows the important elements in each heat and the proportions of each. This permits closer control over the molten foundry iron and steel, and means that uniform quality is constantly maintained.

Asked to explain the basis of the method, one of the metallurgists pointed out that salt thrown on a flame causes it, because of the sodium it contains, to burn with a yellow color.

"When burning, each of the other clements has a characteristic color, although many of these colors are invisible to the human eye," he said. "To be able to 'see' the colors—and in that way identity the metals in an aloys—we burn the aloy in a spaik-gap and, with a prism, break up the light it gives off into a 'rambow,' or series of spectral lines. We photograph this pattern of lines By studying the photograph we learn what metals are present in the alloo, By measuring the density of the lines by a very deleate microphotometer we can tell the proportion of each element."

For routine analysis in the Ford foundry, a foundryman pours a special about 1600 feet to the spectrographic laboratory in a pneumatic tube like those used in department stores to transfer change. A laboratory assistant grands one end to make it bright, and in-erts the sample in the 40,000 with spark gap

The tiny casting is quickly cooled and removed from the mold, and a complete record then made of it

After one end of the sample has been ground in the laboratory, it is placed in a 40,000-yoh spark gap, has its spectrum sampshotted

THE HEAT

Complete Analysis of Industrial Iron, Steel by Spectrographs . . . Made During the "Heat" in Few Minutes . . . Necessary Alloying Elements Then Added

Light from the spark-gap goes into the spectrograph, where the prams breaks it up into the spectra mentioned above. The photograph is quickly developed and then analyzed in the microphotometer, which was especially developed, by an application of the "electric eye" principle, for the work. Within 10 minutes, or even less, from the time the sample is poured, the report has been sent back through the pneumatic tube to the foundry foreman. He then orders sulcan, chromium, copper, molybdenum, manganese, or nickel added in just the quantities needed to bring that heat precisely up to specifications. Then it is poured

In addition to close control of quality, the spectrographic method opens up new avenues for research into the characteristics of metals. It also gives the metallurgists a worff method for identifying unknown elements in a mixture and performing smallar jobs which are often extremely tedious by chemical methods of analysis.

As done in the Ford spectrographical aboratory, nine samples may be analyzed simultaneously for six different elements, a total of 54 quantitative determinations, all in a few minutes. The great value of this speed, in a foundry

that pours several hundred tons of cast iron and cast alloy steel a day, is obvious.

Practical application of the spectrogaphic method to routine control of foundry output was the work of Messra. H B. Vincent and R. A. Sawyer of the department of engineering research of the University of Michigan. Its first foundry application was in the Campbell, Wyant & Cainon Foundry at Muskegon, Michigan; and experience gained in the operation there, dictated the changes and improvements incorporated in the Ford spectrographic laboratory. It is the world's most advanced laboratory

Of particular interest to photographic fans is the method used for drying the plates on which the spectral lines are photographed. Time for processing the plates, of course, must be held to a minimum if the speed of the method is not to be largely lost in the dark room. A high contrast, fine-grain plate is used. After a quick trip through the developing and fixing tanks it is rinsed in distilled water, making sure no minerals which might affect the density of the spectral lines remain. It then is dried in about 30 seconds in a special "toaster" consisting of an electric heating element and a blower, and sent to the microphotometer for analysis

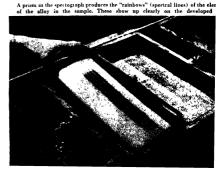

Percentages of elements are quickly computed a report sent to the foundry to guide the fore

The spectrographic plate is then examined in a microphotometer

Light from the spark is sent into a spectrograph which contains a photographic plate

Taken especially for Scientific American by Betty Mendes
Professor Einstein at home in his study

(Part One) The Special Theory

TWENTY years ago, the world, emerging from that cataclysm in whose dark shadow it is even yet engulfed, was electrified by the predictions of a scientific theory of unparalleled boldness, the general relativity theory of Albert Einstein, Hailed as a revolutionary theory, in a field in which heterodoxy then seemed to entail no objectionable sociological implications, it constituted for many a pleasant escape from the war's sordid aftermath of recrimination and disillusionment. Public interest in relativity and its spectacular astronomical consequences was heightened by the journalistic fable that there was, according to its author, but a handful of specialists capable of understanding the theory-a fable branded by Einstein himself as one "invented as a consolation for those too lazy to think!" A hundred books and a thousand articles-a good majority designed for the consumption of "the man in the street"-were written before public interest wantd in favor of Tutenkhamon and things Egyptian, a fad more easily adaptable to the fashions of accoutrement and coiffure.

But these who followed more closely, the development of the general theory of relativity knew that behind it lay Einstein's 1905, or special, theory—the historical, if not the logical, background of the more spectacular theory of gravitation. In many ways of grater importance for the general body of physical knowl-dege, the special theory was the logical

Relativity_

outcome of decades of con flict between the classical mechanics and the growing body of optics and electromagnetic theory. Strange as it seemed at first with its surrender of the concept of absolute simultaneity, it underwent a steady development and clarification in the decade following its inception. The striking paradoxes to which it gave rise, most illuminatingly resolved during this period by the revolutionary space-time geometry associated with the name of its distinguished exponent Minkowski, seem to have attracted but little attention outside the circle of scientists who concerned themselves with fields directly affected by the theory.

By 1918 the special theory was firmly established on the sold bear of experimental findings, and, although logically independent of the general theory, it was thoroughly incorporated as a special case into the latter more embracing dectrue. It, too, then came into its share of general interest, especially in view of its renunciation of the absolute time so universally employed by its predecessors, and the paradoxes—such as that of the traveling twins—to which this renunciation gave rise.

What, then, has been the fate of these two theories during the past two dec-ades—the special theory itself, and the more inclusive theory of gravitation? What of the speculative theory of the "expanding universe," which has been grafted onto the general theory during this time? And what credence is to be given the vitriolic attacks launched recently on the theory and its author by those fanatics who would reform physical science along the lines laid down by political or racial dogma? To answer these questions and, more, to follow the unfolding of these theories during the past 20 years, is the purpose of this article. Let us begin with a review of developments in the special theory, as the question of its validity is quite independent of the validity of the later general theory-although the converse of this statement is not true.

First, we consider the status of the historical Michelson-Morley experiment, which has undoubtedly served, more than any other single experiment, to initiate that train of thought which was to cul-

minate in the special theory of relativity. As pointed out by Maxwell in 1878, if light is propagated through a stationary ether with a constant velocity, then the motion of an observing apparatus through this medium should give rise to optical effects which would, in principle at least, enable the observer to determine his velocity with respect to the etherhight should under these circumstances take longer to travel a given distance down the ether stream and back than to travel the same distance across and back. a discrepancy which should be observable with the aid of a suitably designed apparatus for the detection of interference between the two re-united beams. And, since the Earth is traveling around the sun with a speed of 30 kilometers per second, in the most unfavorable case its maximum velocity relative to the hypostacized other must be at least this large—unless the ether is substantially entrained by the matter composing the Earth, in which case there would be great difficulty in explaining the well-known phenomenon of aberration of light from the stars. In spite of the minuteness of this "second order" effect-depending only on the square $(v/c)^2$ of the ratio of the velocity v of the observer to the velocity c of light-its detection seemed well within the range of observational technique. Experiments on this effect at the Case School of Applied Science in Cleveland, carried out by Michelson and Morley in 1887 and by Morley and Miller around 1905, failed to reveal this predicted effect; their results were, at the beginning of the period covered in this report, generally taken as a confirmation of the theory of relativity, according to which there should be a null-effect. But in 1925 D. C. Miller announced that a careful repetition of the experiment on Mt. Wilson showed, not the predicted result, but one which he could explain only by assuming that the solar system was moving some 200 kilometers per second through the light-bearing medium, and that this medium was entrained by the Earth to such an extent that the relative velocity in the interferometer house on Mt. Wilson was reduced to a mere 10 kilometers per second. As such an effect would be extremely difficult to explain by a modification of the classical theory. and presumably impossible on the relativity theory, the question of its existence became of great importance.

LATER experiments by Kennedy and Michelson on Mt. Wilson and Joos in Jens failed to show the effect, although

20 Years After

An Evaluation of the Achievements of the Special and General Theories of Relativity During the 20 Years which Have Elapsed since the First Direct Observational Test of the General Theory

By H. P. ROBERTSON, Ph.D.
Professor of Mathematical Physics, Princeton University

the apparatus employed by the former and the latter should have been capable of detecting a relative velocity of as little as one kilometer per second! Miller's suggestion that this null-effect might be explained by assuming that the more substantial housings in which these experiments were performed might be responsible for a further entrainment of the ether, seems untenable in view of the most simple and ingenious experiment performed by Hammar of Idaho in 1934. Hammar reasoned that such an explanation would lead to an easily detectable "first-order effect" (depending on the ratio v/c itself) if one arm of the interferometer were encased in a heavy tube; with such an apparatus, capable of showing a differential entrainment of one kilometer per second, no such effect was observed. That the highly mystifying effects predicted by the Englishman Hicks, Cartmel of Montreal and others, due to imperfect alinement of the apparatus. are in fact spurious was shown by the more complete analysis published by Kennedy in 1935. The bulk of the evidence is thus directly in favor of the null-effect, and hence indirectly in favor of the relativity theory, although a completely satisfactory explanation of the outstanding exception, the Miller experiments, has not to date been given. One interesting possibility which has been suggested is that Miller did not adequately allow for magnetostriction, due to the action of the Earth's magnetic field on the interferometer base, but to my knowledge no independent analysis of the data, with this feature in mind, has been carried through.

A DIRECT confirmation of the validity to of the second order term in the relativistic expression for the Doppler effect was announced last spring by H. E. Ures of the Bell Laboratories. By an ingenious arrangement of mirrors lives was able to observe the Doppler shift in an oncoming hydrogen beam, and at the same time the shift due to the recession of the same beam; on comparing the cen-

ter of gravity of these two shifted beams with the undisplaced line, the predicted term was verified, although the displacement was just about at the limit of the resolving power of the optical system.

Surprisingly enough, the keen analysis carlier last year by Zahn and Spees, of Ann Arbor, of the fundamental experiments of the German physicists Bucherer and Neumann, long accepted as establishing the relativistic variation of mass with velocity, shows that they actually prove little more than an increase of mass, as the resolution in these older experiments is too poor to give quantitative results, Because of the general belief in the validity of these original experiments, little, if any, advance in this direction has been made since their performance-with the result, as emphasized by Zahn and Spees, that "in view of the fundamental importance of such experiments it seems that much is left to he desired." It is to be hoped that this challenge will soon be met, and that, with the aid of modern technique, we shall obtain a surer knowledge of this effect for particles of high velocity.

Another result skirted upon by electromagnetic theory, and more definitively expressed by relativity, is the equivalence of mass and energy. This effect, which has long been speculated upon as a possible-perhaps the only possiblesource of stellar energy, has been employed as one of the most important theoretical tools in the recent developments in nuclear physics. The consistency of the modern table of atomic weights, usually given to four places after the decimal point, under nuclear transformations may be regarded as a most valuable indirect confirmation of this equivalence. This growing body of knowledge gives great promise of yielding an evolutionary interpretation of the main features of the Russell diagram relating the luminosity of a star to its typepromise the fulfillment of which has been materially furthered by the recent work of Bethe of Cornell, and of Gamow and Teller of George WashPROFESSOR Einstein published his special theory of relativity in 1905, but the published his special theory of relativity in 1905, but the published his general theory of relativity completed with its Fatile Quarter and again failed to give notice. An eclipse of the Sun that took place on May 29, 1919, first focused press and public a thoughts toneity on relativity, because this afforded the first actual observational check on the general theory. This present month, 20 years after that pivotal date, is chosen to first of the control of the

-The Editor

ington. Thus the former would consider the stars of the "main sequence" as fed by the energy liberated on the combination of protons and electrons into an α-particle, the by-product of a lengthy chain of nuclear reactions involving carbon and nitrogen.

Finally, the greatest single triumph of the special theory during the past 20 years is its immense importance for the theory of atomic structure. At the beginning of this period it was employed, with great success, by Sommerfeld of Munich to explain the observed fine structure of the hydrogen spectrum. This was followed by the seven lean years prior to the development of modern quantum mechanics, in which the attempt to explain the structure of other spectra was frustrated in large part by the fact that the alkali doublets, whose separation was of the same order of magnitude as this relativistic effect, could for other compelling reasons not be so interpreted. The resolution of this dilemma by the semi-empirical introduction of the electron spin, by the Dutch physicists Uhlenbeck and Goudsmit, and the derivation by Dirac of Cambridge of the spin from accepted principles of quantum and relativity theories alone, constitutes one of the greatest chapters in atomic theory.

In view of these developments one may say that at present the special theory of relativity is one of the most throughly accepted and most firmly established doctrines of modern physes. It has permeated the fields of mechanics, electromagnetism (nedunding optics) and atomic physics; while it may appear desirable to have further direct checks on the validity of its mechanical aspects, a deviation from the predicted effects would constitute a most puzzling—and, at least temporarily, distressing—joft for modern physics.

(Part Two-The General Theory-will appear in July)

Railroading's Latest Chapter

One of the two identical units of the new Union Pacific Steam-electric locomotive. Units may be operated separately of together. Note the engineer's high perch

STEAM is riding the rails in a new

Instead of directly driving the wheels, as it has done in reciprocating steam becometives for the past century, steam has been harnessed to function at increased temperature and pressure through small but amazingly powerful turbines installed in a locomotive And the turbines—that berothers to those installed in modern power plants through small on the country—otate generators to furnish the energy for electric motors to drive the becomotive.

This is the radically new steam-electric locomotive built by the General Flectric Company for Union Pacific's fast passenger service between Chicago and the Pacific coast. It can haul a 12-car passenger train over the 2.2 percent grades encountered on that run and will operate safely at speeds up to 125 miles per hour It will do twice the work of the conventional steam locomotive for the same amount of fuel. The first locomotive of its kind in the world, the steam electric locomotive introduces another type of motive power to rail transportation, and opens a new chapter in the romancestudded history of American railroading.

lust ten years more than a century ago.

Horatio Allen, who had been at the throtte of the Stourbridge Laon on its first trial run in this country, summed up a report to the South Carolina Railroad on the respective economies of steam locomotives and horses with the following words:

"There is no reason to expect any material improvement in the breed of horses, while in my judgment, the man is not living who knows what the breed of

the locomotive is to place at command."
The 'breed' of the locomotive has
certainly lived up to and far outdistanced the possibilities foreseen for it
by Allen And his comment is still true
of any type locomotive in service today

S TEAM transportation, introduced to Knowbrdge Loan in 1829, still provides the mainstay of motive power for the American indirects of the 45,000 locomotives now in service in our country, all but a small percentage of them are of the reciprocating steam type Since the De Witt Clanon hauled as first tain on August 9, 1831 over the 17 miles between Albany and Schenetady in the time of one hour and 45 mountes, commons development and improvement of the steam locomotive has been taking

place.

It was not until 1895 that a new type of motive power appeared on the scene to challenge the reign of steam in rail transportation. In that year the Baltimore and Ohio began operating the first standard railway electric tutuk line. At the time there were many who predicted the electric locomotive would soon replace the then well-established steam locomotive. But it soon became apparent that the electric locomotive could be used economically only where there was

sufficiently heavy main line traffic to justify the expense of erecting and maintaining a costly overhead power system.

Steam's latest important competition came along in 1934 in the form of the Diesel-electric bosomotive and Diesel reliable car In that year the Chicago, Burlington and Quincy Railmad put its lightweight, articulated Zephyr into service between Kansas City, Omaha, and Lincoln. In a short time, the Diesel-electric bosomotive became synonymous with speed and modernity in rail transportation. The sleet.

Interior of the cab showing simplicity of controls and operator's chair

richly appointed Pullmans and passen ger coaches which were flashed acrossthe country by Dwest-electric locomotives quickly captured the imagination of the American public Air conditioning, introduced at about the same time and included as standard equipment on all of the newly built Diesel-electric trains, made, them ever more popular Here was real competition for the timehoured ion horse. So real was it, in Iacl, that immediate steps were taken to maintain the prestige of the steam loce-

In 1937, two streamlined steam locomotives were produced to pull the "Hiawathia" trains between Chicago and Minneapolis at greatly increased speeds. Now streamlining has beener the fashion in steam as well as Direct-electric locomotives, and of the 43 streamlined locomotives produced in 1938, 25 were steam, 18 were Diesel-lectric.

The biggest advantage of the Diesel is its high availability. It can be maintained in continuous service for longer periods than the steam locomotive without stops for rest and overhauling and

Steam and Electricity Co-Starred . . . New Locomotive Has Advantages Over Present Motive Power . . . Thermal Efficiency High . . . Unique Features

By C. P. FISHER, Ic.

can travel greater distances without stopping for fuel of water. The cost of Diescl operation will not exceed two thirds of that for an equivalent steamer.

But initial cost still favors the steam becometred It costs only one quarter to a third the delivery pine of a Diesel electric of equal power and speed. The Diesel, however, has greater tractive effort at low speeds. For that reason it has become extremely popular in withing service on radioads and in industrial plants.

No comparison is available as yet on the operating or maintenance costs of the new steam-electric and Diescle-electric types of locomotives, but it is expected that those of the former will be lower. The steam-electric locomotive has its fuel

One of the two main drive turbine and gear units being assembled

fed into a fire box rather than into a combustion engine and for that reason can burn a very low-cost petroleum, known as 'bunker C" oil

In essence, the steam-electric locomotive combines the inherent advantages of both the reciprocating steam locomotive and the straight electric locomotive, plus the reliability, efficiency, and compactness of the steam turbine, a prime mover proved beyond a doubt in thousands of central stations. The steam turbine has no reciprocating parts, no lubrication difficulties, and when properly applied is most efficient in the use of fuel It is this combination of the proved advantages of the steam locomotive, the electrical locomotive, and the steam turbine which makes the steam-electric locomotive most interesting

DISCUSSIONS of plans for building the steam electric locomotive were taking place even before the Diesel-electric locomotive loomed as a factor in the transportation industry Space limitations presented one of the principal problems in building the steam electric locomotive A steam turbine for a power plant night sprawl out to any reasonable proportions, but there were definite limitations in building one to generate power in a locomotive Locomotives' dimensions are restricted because of clearance requirements of bridges and tunnels Length cannot exceed that point at which flexibility for rounding curves is lost

The Union Pacific steam electric locomotive consists of two identical units,

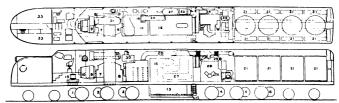

View inside the cab nose showing some of the train control equipment

each 90 feet 10 inches long, weighing 530,000 pounds, and rated 2500 house 530,000 pounds, and rated 2500 house between Each is complete in itself and may be operated individually as an independent locamotive, or the two may be operated in multiple under the control of a single operator. As an incidental point of interest, this is the first time in the world that two steam powered locamotives have been operated in multiple unit.

The sides and toof of each unit are of sheet aluminum, climinating unnecessary weight, although the noise of the cabs are of ordinary carbon steel. The cab-frames are built of high-strength steel tubular members.

Each motive power unit not only supplies the rated 2500 horsepower for traction purposes, but also supplies the power for auxiliary electric power through out the train, as well as the steam for heating the trailing coaches.

The main turbine set of each cab is self-contained with high- and low-pressure units mounted on a common base (Please turn to page 388)

Compact arrangement of the equipment in the new steamelectric locomotive. By the numbers 1 to 6, traction motors; 7-8, main generators; 9, alternators; 10, exciter; 11, battery charging set; 13, main control contactors; 14, battery; 16, boller; 18, high-pressure main turbine; 19, low-pressure main turbine; 20, exhaust heade; 21, an-cooled condensers; 23, high level condensate tank, 28, boiler auxiliary set turbine; 26, compressor; 31, train heating evaporator; 33, raw water tank. This concentration of equipment, unique in its conception, had to be exrited out under tight dimensional limitations

Sulfanilamide and Sulfapyridine

GREAT discoveries in chemotherapy are rare. For all the prodigious efforts spent in the attempt to discover drugs having marked action in germ diseases, today there are only a few great specifics, such as quinine for malaria and the arsenical for syphilis.

We must then regard recent progress in the development of powerful chemotherapeutic agents as the opening of a new era. Within less than four years, two chemical agents of outstanding value to medicine have been introduced.

One, sulfaniamide, has gamed established application in treating, often curing, a number of acute infections caused by particular strains of bacteria—the soscalled beta hemolytic streptococci of eryspielas, childbirth infections, blood infections (septicemia), septic sore throat, meningitis, and it has revolutionized the treatment of gonorrhea. It may or may not turn out to be beneficial in certain types of pneumonia, though conservative meveragetors are doubtful.

The other, salfappridate, a feed was the victorial transfer of sulfanilamide, already appears to the salfappridate, already appears to the salfappridate, already appears to the salfappridate of the

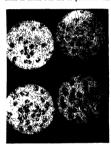

WHETHER or not pneumonia therapy is advanced through these new drugs, both of them are specifics of rare importance. The discovery of sulfapyridine so soon after the introduction of sulfanilamide indicates that in this group of chemical compounds we have molecules exhibiting priceless physiological activity. Where one derivative of sulfanilamide is so potent, there must be other derivatives as powerful in their therapeutic action, not only against the bacteria already brought largely under control but against other germs. Study of sulfanilamide and its kin molecules brought sulfapyridine. Further studies will probably give man additional weapons against his subtlest enemies.

The existence of the sulfanilamide (para-amino-benzene-sulfonamide) molecule was discovered in 1908, by dye chemists. In 1913, the possibility of using such dye molecules in chemotherapy was suggested, and a number of these sub-

Now that Enough Time has Elapsed to Permit Calm Estimate of These Newly Developed Drugs, How and Where do They Stand in the World of Medicine?

By BARCLAY MOON NEWMAN

stances were subsequently found to have limited value as anti-bacterial agents. In 1935, German scientists, guided by G. Domagk, determined that prontosil, which contains the sulfanilamide structure, is effective in streptococcus infections in mice. The use of prontosil was

Some of the bacteria against which the new drugs make successful war. The bacteria are the tiny dots

promptly extended to man, in clinics throughout the world. Finally, the most active fragment of prontosil was shown to be para-amino-benzene-sulfonamide, or sulfanilamide. Prontosil and a derivate, neoprontosil, however, do seem to have certain unique applications in this field, where sulfanilamide and sulfapyridine are not quite so efficacious, and also grare considered by most investigators to be as valuable in general as the less complex molecules.

There are three forms of bacteria: rods, spirals, and globules—all micro-copic. The globules are cocci. Occi which characteristically multiply so as to produce chains of globules are streptococci. Staphylococci are those forms which reproduce so as to give rise to clusters of individual bacteria.

Streptococci are man's worst bacterial enemies. They are found practically everywhere, hence are an ever-present menace. And they cause a greater variety of infections than any other type of bacteria. The most dangerous strep tococci are the hemolytic-those with destructive influence on the red corpuscles of the blood. Further, there are numerous strains of hemolytic streptococci, the beta strain being outstandingly diabolical. Beta hemolytic streptococci cause septicemia ("blood poisoning"), mastoiditis, acute tonsillitis, septic or epidemic sore throat, erysipelas (acute inflammation of the skin), scarlet fever, and several other pathological conditions. Prontosil goes into history as the first drug to be effective against these bacterial invasions, Except in the case of scarlet fever, where serums are now available, no direct treatment, not even a partially beneficial serum, was known to medicine before prontosil and sulfanilamide.

NEITHER sulfanilamide nor any related compound is "a three-day cure" for gonorrhea, which is caused by a coccus that characteristically multiplies so as to produce pairs of bacterial balls and hence is known as diplocourthen new drugs are remarkably active here too, but weeks are always required for a cure—and a considerable percentage of the sufferers are not at all benfited by the drug. Yet the therapeutic agents have no equal in their powerful action on this occus.

Such successful drugs as prontosil and its active fragment, sulfanilamide, stimulated feverish research among the world's pharmaceutical chemists. Hundreds of sulfanilamide derivatives have been synthesized and tested on infections in experimental animals and on human beings in the clinic. Last year, the English medical scientist, L. E. H. Whitby, published a paper describing his experiments with 64 different molecules. Of these drugs, sulfapyridine showed unique promise, as tested on infections in mice. Generally duplicating, if not surpassing, the beneficial activities of sulfanilamide, sulfapyridine in addition was proved strikingly effective against the staphylococcus, the pus coccus of boils, carbuncles, and most of the other

common pus-producing bacterial invasions. Sulfanilamide is practically valueless in staphylococci invasions.

Whitby's pioneer labors have been immensely extended. Sulfapyridine, if it does not ultimately turn out to be too poisonous, is going to be used more and more against staphylococcus and may replace sulfanilamide in many treatments, perhaps in gonorrhea therapy.

In fact, both sulfanilamide and sulfapridine (and, of course, closely related compounds, such as prontosil) are highposon, because its very activity is dependent upon its power over life reactions. So toxic are these new chemical agents that the government forbids then sale without a prescription. And, as yet, sulfapryidine has not been released for general sale in drug stores, even if prescriptions were available. Use is re-

stricted—wisely—to the leading medical experts. The experimental phase has not been passed. Great care is excised with sulfappridine: experience has taught that the sufferer who treats himself with sulfanilamide is hable to kill himself.

TYPICAL view of the A TYPICAL VA. is that of Dr. Reuben Ottenberg, of the Mount Sinai Hospital, New York City, who sums up his study of hundreds of cases in the New York State Journal of Medione. "We are dealing with a treacherous drug-one that has enormous therapeutic value and therefore cannot be abandoned, which nevertheless, on rare occasions, due to idiosyncrasies which have as yet no explanation, may de-

velop the most destructive effects. In pite of the rapid and brilliant cures which can usually be effected, the physician should not be tempted to give the drug for minor infections. Sulfanilamide seems to be most valuable against microorganisms which are rapidly spreading, are more or less free in the tissues, or are in the general circulation.

Sulfanilamide and certainly sulfapyridine are best administered to a patient who is kept in the hospital, under close supervision. Almost daily observation is necessary, especially where the patient has not been hospitalized, and is liable to overdose himself against the advice of his doctor, or is liable to develop some sudden reaction.

Reactions are numerous and varied. "Patients who are receiving sulfanilamide therapy," advises Perriin H. Long, of Johns Hopkins, in *The Pennsylvania Medical Journal*, "should be warned against driving automobiles because the

Right: Girls filling bottles with neoprontosil tablets. Prontosil, neoprontosil, sulfanilamide (terminal syllable pronounced "mid" in spite of spelling), and sulfappridine are all closely related compounds

Below: Filling vials with neoprontosil solution, in glass-enclosed hoods and under sterile conditions and surroundings

dizziness and decreased mental keenness sometimes seen in the course of therapy with the drug render many individuals dangerous on the road"

Other untoward results are rashes, extreme sensitivy to light, sudden severeanemia, fever, headache, nausea, acute acidosis, loso of white blood cells, temporary msantty. But, in experienced, careful hands, sulfanilamide is not only invaluable but safe—no deaths occur, and recovery from adverse symptoms due to the drug is sure and complete. Sulfanilamide elaredy saves thousands of lives annually. And the probability is that sulfappritien will do likewise.

Totic manifestations to sulfapyridine copy those caused by its chemical relatives, as is generally the case in physiology. Sulfapyridine may or may not be more toxic than sulfanilamide. Nobody knows for sure, yet—but it is beginning to seem that sulfapyridine is slightly the more dangerous of the two, though

on contraw Windows Chemial Cs. 10st by no means excessively dangerou-These new agents are prepared ascrystals, as powder, and in solution. Administration by mouth is preferred, but injections are necessary in certain conditions, as where the patient's digestive system is up-et Sodium hearbonate isnuariably green along with the drug, because of the danger of acidosis. And, as-Dr. Long and his colleagues recent: "We

cannot stress too strongly the fact that

the patient who is receiving the drug

needs the intelligent and careful super-

vision of the physician."

T is now established that the chief factor in successful therapy is the maintenance of a certain rather high concentration of sulfanilamide or sulfapyridine in the body, over a period of days. The chemicals are extremely valuable in that they diffuse almost evenly throughout the tissues and tissue fluids, even penetrating in beneficial concentration into the most secret focus of infec tion, the chief spawning place of the germs. So efficacious are the new drugs. especially in gonorrhea, that recovery is often dramatically sudden-and the germs apparently disappear completely within a few days. That is why sulfanilamide has erroneously been called the "three-day cure"-and why many a seemingly cured individual may become a walking source of infection, and may himself suffer a new attack from germs not harmed but merely lurking deep within the tissues. Now, with our first wave of over-optimism subsided, we know that no cure is sure unless the case is followed through a full six-month period.

What is the explanation of the action of the new chemotherapeutic molecules? If the drug chemist knew the answer, he could discover whole systems of chemical agents, each valuable in a unique way This mystery is for future research A new era is before us.

COLD LIGHT

PureFiles have long excited the curiosity of man. The first recorded attempt to make a scientific study of their light was that of Robert Boyle, who their light was that of Robert Boyle, who may be a supposed in the 17th Century. Boyle placed fireflies under the bell jar of his vacuum pump and gradually exhausted the air As the air supply became thinner the glow became less intense, until finally a point was reached where it died out al-

iogether.

In our own country, Professor E N.
Harvey, of Princeton, undoubtedly is the
most outstanding of all investigators in
the field of bioluminescence, or light production by animals and plants. Professor
Harvey has found that the luminous material of the firefly consists of two chemical substances, which he terms

"luciferin" and "luciferase." Neither of these contains any phosphorus, as is commonly supposed by many persons. They are both protein-like in nature, but their exact composition has never been determined. It seems likely that it is the luciferin which actually produces the light, while the luciferase acts as a catalyst-that is, it stimulates the light-giving reaction to take place, without undergoing any appreciable change itself. The light occurs when the luciferin comes in contact with the oxygen of the air in the presence of the luciferase. The presence of water is also necessary for light to occur. In a dried condition the luminous organs will keep indefinitely. Once the writ er dried about 500 fireflies, then removed and pulverized their luminous organs, Several years lat-

er this powder, when moistened, still would glow with undiminished brightness.

The light-giving organs of the firefly

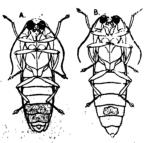

The hght-grung organs of the firrily preent a marvelously complex structure. They occur on the under side of the last two segments of the abdomen. Just above these luminous cells, embedded in the body of the unsect, there is a highly efficient reflector. This consists of a layer of intime models of the control of the co

If Man Can Discover the Secret of the Firefly, the Effect will be Far-reaching . . . Experiments in Which Man Tries to Imitate Nature's Successes

By EVANS W. COTTMAN

light. An injured firefly will sometimeemit a continuous glow, and this is because the organs controlling the admission and expulsion of an have been impaired, allowing a constant small supply of oxygen to find its way into the tubes.

The question is often asked: Of what use is this light to the firefly? The light serves as a means for bringing the sexes

Location of luminous organs on under side of firefly, shown by shaded areas. A is the female, B, male

together. Each sex and each species has its own characteristic light and its own methods of flashing. Some have a yellowish flash, while others have a bluish green. Likewise, some flashes are long and deliberate, while others are quick and nervous. Professor Ulric Dahlgren, of Princeton University, some years ago devised a tiny electric flashlight with which he was able to imitate the color and style of flashing of various types of fireflies, and with this he was repeatedly able to attract large numbers of male fireflies by mitiating the females' flash.

The eggs of the firefly are laid in late spring or early summer, around the roots of grasses in damp, moldy places. At the end of about 22 days, the luminous organs begin to develop within the eggs and the eggs begin to glow. These hatch in indeumner into tup luminous gruls, the glowworms. The glowworm is the larva of the firefly, just as the caterpillar is the larva of the butterfly. (The nailes is also applied to the adult wingless females of some species). Glowworms hiddening the day, but emerge at night to seek food, then diet consisting chiefly of snails, slugs, cutworms and small earth-

worms. For two summers they eat and grow, but hibernate during the winter. The third spring they emerge again and shortly afterward pass into the pupa stage. Inside the shell of the pupa case wings develop and the light-giving organs change into the adult form. At the end of about 17 days the adult firefly emerges, Shortly afterward it mates, the eggs are deposited and, after a brief life on the wing, the insect dies. The glowworm can easily be distinguished from the firefly at night by its continuous glow, whereas the firefly emits its light only in flashes. Also, the glowworm does not fly. In the glowworm the entire area of the segments of the abdomen do not give off light, the luminous areas being limited to tiny spots.

Interesting as our own fireflies

are, others in foreign lands are more spectacular. In South America there is a species called locally the automobile bug because it has a white light in front and a red one behind. In New Zealand there is a large underground cavern, its walls and ceiling frequently covered with millions of glowworms. The interior of the cavern is well libuminated by them. The Sumatra glowworm is famed for its brilliance, It possesses 38 spots of light. One species of beetle in South America gives such a brilliant light, that it is sometimes collected by the natives for illuminating their homes.

Besides fireflies, numerous other animals and some plants give off light. Any one living near the ocean has probably at some time noticed a dead fish, in the early stages of decay, emitting a greenish light after dark. This is caused by a certain type of marine bacteria. A story is olid of a butcher whose shop acquired the reputation of being haunted. The meats had become infected with luminous bacteria and glowed at night. These bacteria can be artificially grown in a suitable leguld culture medium. They exit a constant steady light which attains its maximum in about two days. This light serves the bacteria in no way known to man, if at all, and secure to be merely incidential

Batteria cannot be stimulated into emitting light by mechanical shock, electric shock, or heat. A slightly alkalmic condition is more favorable for light production and no light is ever present in an acid medium. Bacteria have been concentrated into a small space by centrifuging

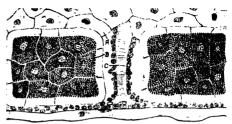

whirling them about at a high rate of speed Such concentrated suspensions of immious bacteria glow with greatly increased brilliance, emitting sufficient light to enable one to read print at a distance of several feet from the light

Human perspiration and the urine of animals have been observed on rare ocasions to glow in the dark. Generally this has been as ribed to the presence of bacteria accelerally taken into the stomach on food. While this may be the case, the writer has found that various exercitory products are themselves luminous when monerly oxidized.

Many mushrooms and other fungi comtain substances which glow when extain substances which glow when exposed to air, Especially is this true of the insert, from which the mushroom grows. This inyclum permeters the decayed wood from which they may appear and, if the wood be torn apart, the thers of the mushroom grows and the properties of the procording to the air. This causes the glow called forshre, which often has been observed on damp rotten wood.

In many localities the sec contains myraids of Northera, httle on-cycled annuals which will crul light when disturbed. A boat passing through such was ter leaves a wake of golden light, due to the disturbance of these organisms. The sands near the shore are left saturated, when the tide goes out, with water containing these tmy living forms. Treading upon these sands disturbs them, and thus footprints of golden light are left impressed upon the sand.

The luminous deep-sea fishes have long been a source of interest and wonder and many articles have been written on them alone. Some have rows of lumnous spot sunning along their sides, giving them the appearance of ministure ocean lumerating at night. Perhaps the most interesting is the deep sea angler. This fish has a long stalk extending out from its head. On the end of the stalk there is a "light bulk," surrounded by little appendages which look like worms. This luminous device hangs just in front of the fish's mouth. The light and the "worms" attract small-rakes, they are fashes, which of course places them in

A highly magnified section through the luminous organs of a firefly, A representcells of the reflecting layer, B. luminous cells, the little dots being granules of lufferin C. air tube admitting oxygen to luminous cells. D. transparent skin over the lower surface of the luminous segments of the abdomen. The light produced in the cells B is reflected out through D by cells A, as is described in the text

the most convenient position for the large fish to swallow them

Among other luminous forms of animal life are numerous kinds of jellyfish, sponges, marine worms, earthworms, centipedes, brittle stars, mollusks, shrimps, crabs, cuttlefish and squids, the total number of species running into many thousands. One species of squid has luminous organs on the ends of its tentacles. It flashes these like a firefly. One of the most brilliant of all luminous animals is Cypridina, a small marine ostracod crustacean. In this animal the luciferin and luciferase are discharged into the surrounding water, producing a brilhant blue lummescence, Dr. Harvey used this animal extensively in his researches,

SINCE nature has supplied cold light in so many forms, it is natural that man's interest should be stimulated, and that he should fir yto imitate hei. In 1877 the chemist, Radrisewski, prepared be plune and decovered its luminescent properties when oxidized Loplune gives a beautiful yellow light Directions for its preparation and treatment have been stated in Seisentific American Jaugust, 1937, page 120 – Edd. The writer has prepared about a dozen directive view for his prepared about a dozen directive so prepared about a dozen directive so prepared about a dozen directive so present a present in the present in th

An orange-red luminescence can be produced by treating pyrogallol (commonly used in photography) with for maldebyde and hydrogen peroxide in strong alkaline solution. Dr Harvey produced light by oxidizing pyrogallol with

peroxule and potato juice.
In 1923 W. V. Evane and R. T. Dofford
described a series of luminescent compounds which they had prepared. These
belong to the class known chemically as
Grignard compounds, and one of them,
p-chlorphenylmagnessium brounde, gave
the brightest chemi-luminescence that
had yet been produced.

In 1929 the German chemist, Albrecht, discovered a chemical which, when oxidezed, gave forth the most intense and brilliant cold light thus far known. This chemical has received considerable attention in this country, and much research work has been done on it by Dr. E. H. Huntress of the Massachusetts. In statute of Technology. The chemical name of this compound is 3 ammophthallivities acide. For convenience Dr. Huntress has proposed the term "hummol" Upon oxidation it produces a brilliant blue cold light which makes a striking display when demonstrated before an audience

The writer has developed a luminol preparation in a dry powder form termed chemglo." As this powder contains the correct oxidizing agents, it is necessary only to add it to water in order to produce luminescence. An accompanying photograph was taken by chemglo cold light

One would hardly expect to get light out of sugar, starch, and such compounds, but that is what I am doing in my ladorators. This type of compound does not uself give visible light upon oxdation, but does so it heard of flux of first, and then oxidized. The following compounds have been subjected to this treatment with positive results: cane sugar, glucoes, levulose (fruit sugar), ladores (milk sugar), galactoes, starch, dextrin, gum arabot, tartaire, laetie, mahe and citiu eards. The citire acid seems to offer exceptional possibilities, as the flash from it is unusually brilliant.

The cold light described thus far he longs to the class known as chemulum necence. It is in every case caused by chemucal action—the oxidation of some chemucal compound, usually organic Their are, however, many other types of cold light, some of which have been studied much more than chemi-lumine-cone. When an electrical discharge is sent through a vacuum tube containing traces of various gases, a brillant cold

A photograph taken by light produced by a luminescent chemical in solution in the nearer vessel illuminating the other Kodak Bantam Special, 10 min., f 2

electro-luminescence may occur. Radioluminescence, derived from radium, isused on the dals of 'radium' watches and clocks. Grystalli-luminescence is temission of light when certain substancecrystallize from solution. Tribe-luminesence is the production of light when some kinds of crystals are mechanically crushed. Bio-luminescence is applied to the light given off by animals and plants; it is a kind of chemi-luminescence.

FLUORESCENCE occurs when light of one wavelength or color is changed and emitted as another color. Fluorescent substances may appear brilliantly colored in the dark when exposed to ultra-violet rays, the so-called black light. These colors immediately disappear from a fluorescent substance when the black light is turned off, but if the light persists for a time after the ultra-violet rayare removed, the phenomenon is called phosphorescence, A phosphorescent min eral may glow for several hours after having been exposed to sunlight. The term was originally derived by suggestion from the element phosphorus, which glows in the dark. However, in the present sense, it is a misnomer, as phosphorescent substances have nothing to do with phosphorus. It was formerly thought that fox-fire, and all lights produced by animals and plants, were in some way connected with phosphorus. This has been found untrue, and the term luminescence is used in place of phosphorescence for describing this phenomenon.

One of the most surprising discoveries in the realm of cold light has been made by Dr. Leslie A Chambers, of the Johnson Foundation for Medical Physics in the University of Pennsylvania. He has produced visible light by means of sound waves. He places a powerful vibrator in a liquid and causes it to vibrate at a hub. frequency. When this is done many liquids emit light. He reports that viscous liquids at a temperature of about 77 degrees, Fahrenheit, are most favorable for this type of lumnescence, which he has termed acoustico-luminescence. He produced his brightest light from glycerin, which is very viscous.

The first question asked by the practical reader after all these considerations will be: "What use can be made of cold light?" At present we must admit frankly that we do not know. The study of this subject is in its infancy; the phenomenon is, as yet, regarded as a laboratory curiosity. Yet, practical-minded scientists are continually lifting just such laborascience and finding applications for them. It is certain that Oersted could never have dreamed of electric motors, telegraphs, and our long list of electromagnetic appliances when he was making his first interesting studies of the relation of magnetism to electricity.

Cold light seems to have certain theoretical possibilities. It is the most efficient light known. Most lights expend from 95 to 98 percent of their energy in the form of useless heat, Cold light, on the other hand, expends from 90 to 98 percent of its energy in the form of pure visible light. There is scarcely any perceptible heat loss. The intensity of the light, however, is so small that it would require a large light-emitting surface to illuminate a room thoroughly. The present costs of materials would make such a method of illumination impracticable, It will first be necessary to discover brighter and cheaper cold light chemicals.

Occasionally in newspaper articles the claim is made that the secret of the firefly has been discovered. Such articles usually have reference to luminol. This indeed, a brilliant cold light prepara-

tion, but is far from being the answer to the firefly's riddle, If the secret of the firefly were really to be discovered, the effect would probably be far-reaching. The firefly is one of the most efficient organisms in the world. Not only is its light efficient from the standpoint of visibility, but in economy of fuel consumption it is even more remarkable. When the insect flashes, its luminous material is oxidized, giving off light. During the time that the organs are dark, a reversal of this process takes place, and the products of the oxidation are reduced back to their original condition, ready to use over again. It is much as if one could burn a log, then catch the smoke, gases and ashes, and put them together to remake the log.

Possibly cold light will prove to have more uses in the field of medicine than in illumination. I have obtained light by the oxidation of urine and a number of the isolated products of metabolism. Also I have frequently used blood to oxidize such compounds as lophine and luminol. A very good light can be produced from the oxidation of urine by blood, in alkaline peroxide solution. In the laboratories of the Eli Lilly Company I obtained measured amounts of blood from an anemic gumea pig, likewise from one which had been rendered normal by giving it liver extract. The two samples of blood were used to oxidize lophine. A very perceptible difference could be observed in the amount of light, the latter sample being the brighter. While little has been done in this direction, it seems quite possible that a technique might be developed for using such phenomena as an index to certain physiological conditions, If these physiological lights could be amplified and made the subject of intense spectroscopic study, the horizon of possible applications would be immeasurably extended.

DR. GEORGE CRILE, of Cleveland, has made some investigations in the field of physiological radiations. He has caused animal brain tissues, reacting to chemicals and gland secretions, to give off visible light. Dr. Crile feels that the luminescence affords experimental evidence that the brains of animals and man may produce their own light, and "that the sun shines again in the protoplasm of animals." He believes that consciousness and such mental processes as thinking may somehow be connected with these mysterious emanations from the brain's supremely delicate tissues. It seems quite certain that all the materials necessary for luminescence are present in the human body. Normally, these are not brought together, but if this were to occur abnormally, it might explain the occasional luminosity reported as occurring in certain rare individuals--a woman in Italy, for example,

Color on a Huge Screen

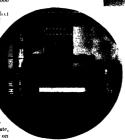

IN a continuous flow of glowing color, single scenes of groups of scenes fill the 187-foot long screen that is part of the Eastman Kodak Company's exhibit at the Now York World's Fair This gainst display of modern color photography is made possible by new twin processes, 110 of which are concealed in a projection booth just under the roof of the ball. Through each of their gate-stabs a brilliant beam of light Triny color-film transparences, about 1 by 125 inches, made on standard Kedachtome film, pass these gates—to become full-color screen pictures approximately 50,000 times larger than the original.

times larger than the originals.
Each of the screen pictures is 17 feet
wide and 22 feet tall, and eleven of
them exactly filthe 187-foot screen
It is interesting to note that the
transparencies which produce
these enormous pictures were
made with cameras similar to
those used by many amateric
photographies.

panotographers
As each small transparency
comes into position, it is registered in place to an accuracy
of plus or minus 1; 10,000 of an
meh, through a combination of
optical and mechanical registration. This same registering system
operates so that even while the transparency is in motion in the projector gate, the
ist enlarged image is held rock-steady on

tures can be changed at different speeds—one group of pictures remaining on the screen a half-minute while others are changed up to four times a second, Fades, dissolves, motion effects can also be presented

The "heart" of the projection system control is a specially notched sound-film, which not only carries the voice of a commentator and special musical accompan-

Top. raph. One of the twin projectors, partly assembled Behind the lens at the left is shown one of the lamp houses and heat filter. In circle-The rectangular piece of po-tical glass that registers the film transparencies exactly, In this view. the film slide is slightly high in the gate; the registering plate is automatically tilted to provide correction. Left: Bolting the slides on the "drum" gen

the screen-no motion can be detected

Each of the hidden projectors is synchronized with the others by an electrical interlock—operating through a fully-automatic control system. Through its electrical interlock and control mechanism, the projection system can be operated with infinite flexibility. If desired, pie-

ment, but also regulates the movement of the projector shutters and the shifting of slides—keeping pictures and comment in perfect synchronism.

Employed in the projectors are large fine-pitch precision ring spur gears, each one 45 inches in diameter and carrying 1440 teeth, On these "drum" gears are

To link the gear-rings with the automatic indexing system, the projectorsemploy one of the largest single-steppur gear reductions even attempted— 48 to 1. The 45-inch grars work directly from a 15-0-inch puino.

E ACH color slide carries a series of gear teeth, integrally mounted along its edge. Together, these teeth form a continuous series around the film ring, and serve to operate the optical regi-tering system built into each film gate This registering means consists of a small rectangular plate of optical glass, which spins as the film ting rotates. As each picture moves into position, this glass wings upright before it. If the picture halts a trifle too high in the gate, the registering-glass remains tilted slightly forward at the top. If the picture stops too low in the gate, the glass tilts back correspondingly, its movement being controlled by the gear teeth on the film. In either case, refraction through the glass shifts the picture-image so that it travels at proper level through the lens, and is correctly positioned on the screen.

The illummating system of each prepector is centrally housed, with the ring gears and film drums revolving around it Water cells are used for cooling, and in addition, a blast of air, chilled almost to the freezing point, is directed on each projector gate. Large-aperture, long focus projection lenses are used, and specially designed shutters are utilized for many screen effects.

WHAT KEEPS THE STARS SHINING?

WE told last month how it can be shown, from the general properties of matter, that a large mass, isolated in space, must be gaseous and very too tinside—millions of degrees, how the heat must e-cape slowly to the surface, and keep this incandescent, and how beserved relation between the mass and the real brightness of a star has thus been fully explained. But the great question why the stars keep on shining remained.

Helmholtz and Kelvin were undoubtedly right in saying that such a gaseous mass, if not otherwise supplied with energy, would slowly contract, drawing on gravitational energy, converting it into heat, storing half this heat or more in its interior, and using the rest to maintain its radiation. But the Sun has been warming the Earth during the whole of geological time-that is for more than 1500 million years, and in this long interval it must have got rid of a hundred times more energy than gravitational contraction could supply. The Sun, and the stars in general, must therefore have some internal source of energy far greater than this.

This would have been perplexing indeed, had not the very same physical disceoveres which revealed the problem pointed a way to its possible solution. It was from radio activity that the cordence came which showed conclusively that the order to the constraint of the contraction of the individual crystals of minerals had lain in the rocks for more than a billion years since their formation; and it was radioactivity, too, which revealed the existence of vast and previously unimagined stores of energy locked up within activity.

To the minute atomic nuclei, therefore, we had to look as the only places small enough to hold so much. (This is not a paradox, but a way of deserthing the enormous magnitude of the forces which act at these minute distances) The obvious suggestion that there were radio-cutve substances inside the stars, which liberated the heat necessary to keep them going, might account for a life of billions of years; but, unfortinately, when it was followed up, it ddn't work.

To begin with, radio-active atoms lib crate energy at a rate which is quite independent of external conditions—temperature, pressure, and the like B₃ as suning the presence of a certain calculable amount of uranium (for example) in the Sun, we can account for the maintenance of its radiation—though the percentage of the whole mass came out rather high. But the more massive stars are much brighter, and radiate For the Source of Stellar Energy We Must Look To Reactions Between Charged Atomic Nuclei . . . Discussions and Background for Bethe's Theory

By HENRY NORRIS RUSSELL, Ph.D. Chairman of the Department of Astronomy and Director of the Observatory at Princeton University Research Associate of the Mount Wilson Observatory of the Carnegie Institution of Washington

much more energy in proportion to their masses. To match this by radio-activity, we would have to assume that the amount of active material had been, in some strange way, so adjusted that the massive stars contained a larger percentage, and those of small mass a smaller, exactly adjusted to meet their needs. It is not necessary to assume (as one would think) that the stars were purposefully made in this way. A star with too little active material to supply its inevitable losses would draw on gravitation for the test, and shrink; one with too much would be forced to reverse the history imagined by Kelvin, and expand If the Universe is old enough, the under-supplied stars might have shrunk out of sight, and the over-supplied expanded into nebulosity, leaving only the wellbalanced ones to be counted But this is hard to believe.

WE do not have to try, anyhow, for another objection to the radio-active theory turns out to be fatal.

A more detailed calculation of the theoretical luminosity of a star shows that, for a given mass, it increases slowly with diminishing size Suppose, then, that there was a perfectly adjusted star. of given mass and radius, and that, in any way, it became a little smaller It would then be a little brighter, and lose more energy. But the radio-active supply would be just the same. It would draw on gravitation for the balance, contract, and get more out of adjustment than before Things would rapidly get worse, and the star would contract "out of sight." If, on the contrary, it should be slightly expanded above the ideal size it would be supplied with radio-active energy faster than it got rid of heat, would be forced to expand further, and again would run wild. A star supplied by an atomic energy source at a fixed rate would therefore be inherently un-"table The process of "running wild" might take a million years (more or less) to get well going, but would be mevitable.

We can get away from this trouble by

assuming that the otherwise unknown at atomic-or sub-atomic-process depends in some way upon collisions between the atoms, and not on happenings in the interior of an isolated atom (as radio-activity appears to do.). We should then expect its rate of occurrence, among the assume number of atoms, to increase with the density, since the atoms would cold bed oftener, and especially with the temperature, since the collisions would be more violent.

Now suppose that we had a star out of adjustment, with the atomic process supplying too little energy. It would draw on gravity for the rest, and would contract This would make the gaseous interior denser, and, as we saw last month, also raise its temperature. The atomic process would then supply more heat. If (as is very probable) this gain in income exceeded the (rather moderate) gain in outgo from the surface which accompanied the contraction, the star would be nearer a balanced budget after the contraction than before. There would be a certain size of the star at which in come and outgo were equal. This would give a state, of equilibrium, and, this time, the state would be stable. Suppose that the contraction overshot the mark Too much heat would then be liberated. but this would force the star to expand, make the interior less dense and cooler. and shut off the over-supply. A star fed by an atomic source at a rate increasing with temperature and density would therefore be self-regulating; it would automatically seek and find a balanced state, in which just enough heat was bherated to supply the natural flow to the surface.

One further complication has to be considered. Suppose that we started with a star that was not quite in mechanical equilibrium—say a little too large, so that the internal gas-pressure did not balance gravity. It would contract, overrun the neutral point, as such things always do, get too small, be impelled to expand, and so find itself in a state of oscillation or pulsation, changing in diameter with a regular period. Edding. ton showed, years ago, that the flow of heat from the hotter to the colder parts of the gas would have a "damping" offect on such an oscillation, gradually reducing its range to nothing—as the friction of the air does to a pendulum.

But, if the heat-supply increases rap idly with temperature, most of it will be liberated when the pulsating star is smallest. This is equivalent to giving the outward motion afterward a little push at every oscillation, which tends to increase the range. If the damping effect predominates, the star, if disturbed, will settle down into quiescence; but, if not, a pulsation once started will increase-probably not enough to break up the star, as it is likely to be limited in extent by additional influences. Many stars are known - the Cepheid and cluster variables-which appear to be doing just this, but the vast majority of the stars are steady-going affairs of fixed diameter Hence our theoretical source of energysupply must not increase too violently with the temperature.

At one time this appeared to be a good controlled to the controlle

So much we can learn from the stars themselves—about the properties which the energy-liberating process must have, if it is to satisfy the astronomical conditions.

WHAT processes of this sort could occur in Nature we must assume, if we can, by appeal to physics—and physics of a very modern sort

Our first aid comes from relativity—
the general relativity which is Einstein's
greatest achievement. According to this,
mass and energy—previously supposed
to be each separately "conserved" and
metstructible—are convertible one into
the other, at such a rate that m units of
mass (grams) are equivalent to me?
units of energy (ergs.)—where c is the
velocity of light.

Theoretically, then, the mass of a body should be increased by heating it, as o adding energy to it. The reason why this cannot ordinarily be measured is that c² is a normous number (9 x 10²⁰), so that a very large amount of energy, measured by everyday standards, corresponds to an excessively small mass. For example, a ton of iron cooling from its melting point to ordinary temperatures liberates heat equivalent to 150

kilowatt-hours of energy, its mass is diminished by 1/160 of a milligram!

When we come to astronomical figures, we find that the Sun radiates into space 3.78 x 10³³ ergs per second. To say that this rate is equivalent to 5 x 1023 horsepower conveys no real significance to us, whether we write out the 23 ciphers or not; but when we divide by c2 we find that the Sun is sending out 4,200,000 tons (metric) of heat into space every second, or 1300 millions of millions of tons every year At first glance this looks a little alarming How long would it be before the Sun was used up, at this rate? We need not worry, the Sun's mass is 198 x 1041 grams, and it would last 15 x 1013 years-15,000 billion.

For the source of stellar energy, then, we must look to some process which changes the mass of atoms, and liberates a corresponding amount of energy When this was first realized, more than a decade ago, we had a free choice between two hypotheses-because there was no experimental evidence at all on the subject. One was that, in some way, atoms were annihilated, while all the energy corresponding to their mass was set free, the other, that atoms of one kind changed into another with a net diminution of the total mass, and liberation of energy. At the present time, we have pretty well stopped playing around with the first idea, for the good reason that it remains purely speculative, without any direct evidence in its favor (so far at least, as regards ordinary atoms) The second notion has meanwhile advanced from the status of a hypothesis to that of an established fact With the aid of the natural projectiles emitted by radio-active substances, and the artificial ones accelerated in cyclotrons and similar devices, an amazing variety of nuclear reactions has been produced in the laboratory, Dozens of new kinds of artificial atoms have been made-some of them in several ways-by breaking down or building up from familiar ones Atomn masses have been measured with great precision by the mass-spectrograph, the energy liberated in the reactions has also been measured, and by comparing the loss of mass with the liberation of energy it has actually been possible to calculate the velocity of light from Einstein's formula. The result is of no great percentage accuracy, but it fully justifies the claim that the equivalence of mass and energy is now a fact proved by experiment

All these reactions occur between the tiny nuclei of the atoms; on their scale, the outer electrons are merely distant satellites, remote from the colliding particles, and not directly affected by what happens to them. They fall into two genral classes—encounters between charged atomic nuclei and neutrons, and between two charged nuclei.

Most of the reactions which have been

produced in the laboratory are of the former type-for the simple reason that the atomic nucleus and the neutron neither attract nor repel one another (except at very small distances, indeed), so that a neutron which happens to be moving almost directly toward a nucleus stands a fair chance of getting near enough to it to do something, even if the nucleus is heavy, and has a large charge. But two nuclei, being both positively charged, repel one another. Even a hydrogen nucleus (proton) with its single unit of charge, is so powerfully repelled that, unless its original line of motion was directed almost absolutely straight at the nucleus, it would be deflected to one side, and would miss it Even if it were correctly aimed, it would be slowed up by the repulsion, stopped, and sent back along the same path, without getting near enough to do any damage, unless its initial speed was very high.

THE very thing, however, which of the laboratory physicist makes them unimportant for the astrophysical theorist. Such reactions happen so easily that, in the interior of a star, a free neutron would not remain free for a thousandth of a second-long ere this, it would have hit some atomic nucleus, gone into it, and either built it up into a heavier one or broken it into pieces. If any of the pieces were fresh neutrons, the process could go on repeatedly-and perhaps explosively, but, so far as present observation goes, this does not happen The neutron is used up in the reaction, and only charged particles come out of it.
